Mezereon was recommended by Dr. A. Ruſſel for a particular claſs of venereal ſymptoms, in the following terms: "The diſeaſe, for which I principally recommend the decoction of the mezereon root as a cure, is the venereal node that proceeds from a thickening of the membrane of the bones. In a thickening of the perioſteum, from other cauſes, I have ſeen very good effects from it: and it is frequently of ſervice in the removal of thoſe nocturnal pains with which venereal patients are afflicted; though, in this laſt caſe, excepting with regard to the pain that is occaſioned by the node, I own I have not found its effects ſo certain, as I at firſt thought I had reaſon to believe. I do not find it of ſervice in the cure of any other ſymptom of the venereal diſeaſe." (Med. Obſ. and Inq. vol. iii. p. 194, 195.) Mr. Pearſon, however, aſſerts, unequivocally, that mezereon has not the power of curing the venereal diſeaſe in any one ſtage, or under any one form, and if the decoction ſhould ever reduce a venereal node, yet there will be a neceſſity for taking mercury in as large quantity, and for as long a time as if no mezereon had been exhibited. Cullen found this medicine of uſe in ſome cutaneous affections, but excepting an inſtance or two of lepra, Mr. Pearſon has very ſeldom found it poſſeſſed of medicinal virtue, either in ſyphilis, or the ſequelæ of that diſeaſe, ſcrofula, or cutaneous affections. The root of ſarſaparilla was brought into Europe about 1530. It was at firſt reputed to poſſeſs ſingular efficacy in venereal caſes; but afterwards loſt all its fame. Sarſaparilla was again brought into notice by Dr. W. Hunter, who adviſed Dr. Chapman to make trial of it in a bad caſe of phagedenic bubo; and the benefit obtained in this inſtance led Dr. Hunter to extend the recommendation of the medicine. Sir William Fordyce ſtated, that ſarſaparilla would quickly relieve venereal head-achs and nocturnal pains, and, if perſiſted in, cure them; that, in emaciated or conſumptive habits, from a venereal cauſe, it was the greateſt reſtorer of appetite, fleſh, colour, and ſtrength, which he knew of; that when mercurial frictions had been previouſly employed, it would generally complete the cure of diſeaſe of the throat, noſe, palate, or ſpongy bones; and that it would promote the cure of blotches and ulcers, ſometimes accompliſh it, *even without mercury;* though, in this circumſtance, there was danger of a relapſe. Sir W. Fordyce ſaid, ſarſaparilla was of little uſe in chancres; but when theſe, or buboes, would not heal, after the employment of mercury, it would often cure, and always do good. He allows, however, that in all venereal caſes "ſarſaparilla is not to be truſted to, unleſs preceded by, or combined with, the uſe of mercury:" and he thought ſarſaparilla would probably always cure what reſiſted mercury. Medical Obſ. and Inq. vol. i.

The celebrated Cullen conſidered ſarſaparilla as poſſeſſing no virtues of any kind; for (ſays he) "tried in every ſhape I have never found it an effectual medicine in ſyphilis, or any other diſeaſe." Mat. Med. vol. ii.

Mr. Bromfield declares, that he never ſaw a ſingle inſtance in which ſarſaparilla cured the venereal diſeaſe without the aid of mercury, either given before, or in conjunction with it. (Pract. Obſ. on the Uſe of Corroſive Sublimate, &c. p. 78.) Mr. Pearſon alſo "contends, that ſarſaparilla has not the power of curing any one form of the lues venerea;" but he allows that it may ſuſpend for a time the ravages of that contagion, the diſeaſe returning if no mercury ſhould have been uſed. This gentleman admits, alſo, that ſarſaparilla will alleviate ſymptoms derived from the venereal virus. He maintains, that the exhibition of ſarſaparilla does not diminiſh the neceſſity for giving leſs mercury. Nocturnal pains in the limbs, painful enlargements of the elbow and knee, membranous nodes, cutaneous ulcerations, and certain other ſymptoms, reſembling venereal ones, are often experienced after a full courſe of mercury. Such complaints, Mr. Pearſon allows, are greatly benefited by ſarſaparilla, and exaſperated by mercury; and he obſerves, that it is from theſe complaints having been miſtaken for venereal ones, that the idea has ariſen, that ſarſaparilla has cured ſyphilis when mercury had failed. Mercury, and the venereal poiſon, may jointly produce, in certain conſtitutions, ſymptoms which are not ſtrictly venereal, and are ſometimes more dreadful than the ſimple effects of ſyphilis. Some of the worſt of theſe appearances are capable of being cured by ſarſaparilla, while the venereal virus ſtill remains in the ſyſtem. When this latter diſeaſe has been eradicated by mercury, ſarſaparilla will alſo cure the ſequelæ of a courſe of the other medicine. Pearſon on the Effects of various Articles in the Cure of Lues Venerea, 1807.

China-root once obtained the character of being a certain ſpecific for ſyphilitic complaints. Its reputation roſe very high, in conſequence of its having been reported to have cured the emperor Charles V. At preſent its medicinal virtues are eſtimated very low indeed; and it ſeems to have now loſt all its advocates. It was firſt uſed in practice about the year 1535.

Cinchona, or the Peruvian bark, has no ſpecific virtue in ſyphilitic caſes, but, according to Mr. Pearſon, if it has been alleged upon plauſible grounds, that guaiacum poſſeſſes medicinal efficacy in venereal pains; ſarſaparilla, where there are phagedenic ulcers; and mezereon, in caſes where there are membranous nodes; ſo bark has a claim to praiſe for its ſalutary agency in incipient buboes, in ulcers of the tonſils, and in gangrenous ulcers from a venereal cauſe. This gentleman has ſeen venereal buboes reduced, though not cured, by it; ſyphilitic ulcers in the throat healed by it, though the diſeaſe recurred; and ſudden mortifications of the penis from chancres terminate in a cure of the diſtemper, with the exhibition of bark, unaſſiſted by mercury. In theſe laſt caſes, Mr. Pearſon conjectures, that, as the extinction of the venereal poiſon could not be aſcribed to the ſpecific virtues of the bark, the abſorption of the virus muſt have been anticipated and prevented by the death of the part. This gentleman acknowledges, however, that there are gangrenous chancres met with, where, after the detachment of the ſloughs, the ſpecific diſeaſe in the part continues, and the ulcer ſpreads, ſo that mercury is indiſpenſable.

Opium has been ſaid to be a ſpecific in venereal caſes; and in the firſt volume of the Medical Communications, ſome facts were publiſhed in ſupport of this opinion. But in the years 1784 and 1785, Mr. Pearſon made ſeveral experiments on the virtues of opium in lues venerea, at the Lock hoſpital. Theſe are related in the ſecond volume of the preceding work. The reſult was very unfavourable to the character of opium as an anti-venereal. In a later work, the ſame gentleman obſerves that he has been long accuſtomed to adminiſter opium with great freedom, during the mercurial courſe; and the experience of more than twenty years has taught him, that when this medicine is combined with mercury, the proper efficacy of the latter is not in any meaſure increaſed; that it would not be ſafe to rely upon a ſmaller quantity of the ſpecific mineral, nor to ſhorten the mercurial courſe at all more, than where no opium has been employed. (On Lues Ven., p. 68, 69.) Though opium may poſſeſs no anti-ſyphilitic virtue, it is unqueſtionably uſeful on other principles, in many venereal caſes. It often prevents mercury from diſordering the ſtomach and bowels; and it will frequently leſſen the irritability and reſtleſsneſs produced by the introduction of mercury into the conſtitution. But, regarded as a ſpecific for ſyphilitic affections, we may conclude with Mr. Hunter, that it has no effect, till mercury has done its beſt, or its worſt. This latter ſurgeon owns that opium has certainly conſiderable effects in many diſeaſes, both in ſuch as are conſequent to the venereal diſeaſe, and in others ariſing from different cauſes. It had long been a favourite medicine with him, not only as relieving pain, but as capable of altering diſeaſed actions. In all ſores attended with irritability, he ſays, a decoction of poppy heads, made into a poultice, is an excellent application. He tells us, he had even ſeen two doubtful ſyphilitic caſes cured by the internal exhibition of opium: but on his trying this plan in an unequivocal caſe of venereal blotches and ſore throat, ſo far was opium from producing the deſired effect, that, after a perſeverance of three weeks, the ſores were rather worſe. Treatiſe on Venereal Diſeaſe, p. 373.

Dr. Storck has related ſome caſes, in which cicuta, or hemlock, is ſtated to have cured ſyphilis, when other remedies had failed. (Lib. ii. De Cicutâ.) At preſent it ſeems to have loſt its character, as poſſeſſing any ſpecific virtue over the venereal diſeaſe. It is not, however, a medicine without its uſes. According to Mr. Pearſon, the extract and the powder of hemlock may be ſometimes advantageouſly given in ſpreading irritable ſores, whether they are connected with the active ſtate of the venereal virus, or they remain after the completion of the mercurial courſe. Cicuta ſometimes does good, when opium will not; and, therefore, Mr. Pearſon thinks it may have other virtues than thoſe depending upon its anodyne qualities. P. 75.

For remarks on the anti-venereal effects of ſaſſafras, juniperus, bardana, ſaponaria, dulcamara, juglans, lobelia ſyphilitica, aſtragalus exſcapus, ammonia præparata, barytes muriata, &c. we muſt refer to Mr. Pearſon's publication.

A decoction of the green rind of the walnut ſeems worthy of more attention than ſeveral other articles. The laſt author ſays he has employed it, during many years, where pains in the limbs and indurations of the membranes have remained, after the venereal diſeaſe has been cured by mercury, and ſeldom without manifeſt advantage. P. 81.

The decoction of the woods and the Liſbon diet drink are famous preſcriptions in ſyphilitic caſes. Where the diſeaſe is doubtful, or mercury diſagrees, or is done with, ſuch remedies may certainly be often taken with benefit.

The powdered antimony and pumice ſtone are to be tied in ſeparate pieces of rag, and boiled along with the other ingredients.

This laſt decoction is reckoned to be the *genuine* Liſbon diet drink, whoſe qualities have been the ſubject of ſo much encomium. Pharm. Chirurg.

The muriatic and ſulphuric acids have been exhibited in venereal caſes with ſome advantage, as they are capable of improving the appearance of ſyphilitic ulcers, and reſtraining for a time the progreſs of the diſeaſe.

But the nitrous and nitric acids have gained the greateſt repute for their anti-venereal qualities. Theſe acids have been tried by Dr. Rollo, Mr. Cruikſhank, Dr. Beddoes, Mr. Blair, and many others, as ſubſtitutes for quickſilver, in the cure of lues venerea. The practice began with Mr. Scott, a ſurgeon in Bengal, who is ſaid to have derived the idea from Girtanner, who ſuggeſted that the efficacy of the various preparations of quickſilver might ariſe from the oxygen which they contained.

A multitude of caſes have been brought forward in favour of nitric acid, as an anti-ſyphilitic; but there are alſo ſome others adduced, which ſeem very decidedly to controvert its claims to that character. It ſhould be carefully remembered, that it is the *nitric* acid, not the *nitrous*, which ſeems to deſerve a further trial in ſyphilitic caſes.

The common way of giving the nitric acid, at firſt, is to mix ʒj with a pint of diſtilled water, the mixture being ſweetened with ſimple ſyrup. This quantity is to be drank, at different times, in the courſe of twenty-four hours, through a ſmall glaſs tube, which is uſed to keep the teeth from being injured. If no inconvenience is felt, the doſe of the acid may be increaſed to ʒiſſ, ʒij, and even, in certain caſes, to ʒiij.

The acid is ſaid to increaſe the appetite, and ſecretion of urine; to cauſe more or leſs thirſt, a white tongue, ſizy blood, and an increaſe in the actions of the whole ſyſtem, but nothing like mercurial ſalivation is produced. It does not agree, however, equally well with all conſtitutions.

The nitric acid is beneficial both in the *primary* and *ſecondary* ſymptoms of the venereal diſeaſe; more ſo, however, in the former. But, in the latter, even mercury itſelf frequently fails, and proves hurtful, ſo that the nitric acid ſuffers no diſparagement from this fact. A change is ſaid to be produced on the diſeaſe, by the acid, in ſix or eight days, and a cure very often in little more than a fortnight.

The oxygenated muriate of potaſh, which contains an immenſe quantity of oxygen, is ſaid by Mr. Cruikſhank to be more efficacious than the nitric acid, in relieving venereal ſymptoms.

Richerand informs us, that experiments, confirming the ſuperior efficacy of mercury, in the cure of ſyphilis, were made for the ſpace of a year, in the hoſpital of the Ecole de Médicine at Paris, before a committee of gentlemen expreſsly appointed for the purpoſe. It is ſtated, that ſome patients derived only temporary relief from the oxygenated fat and nitric lemonade; that a very few got quite well; and that others, after appearing to be entirely rid of the diſeaſe, ſuffered ſuch relapſes as evinced the ſuperiority of the ordinary method. Noſographie Chir. tom. i. p. 352. edit. 2.

It appears to us, that there is one very important circumſtance made out by the trials of various medicines in the treatment of the venereal diſeaſe. According to the Hunterian opinions, we are to ſuppoſe that it is the invariable character of the diſtemper to proceed regularly from bad to worſe, unleſs checked by the ſpecific remedy, mercury. This doctrine is taught in ſome of the preſent ſchools, and ſeems to be adopted by Dr. Adams in his work on morbid poiſons. Were this idea a matter of fact, it would be of material conſequence in practice; for, in many difficult and ambiguous caſes, we might often form a juſt deciſion, by obſerving whether the complaints recede at all, without the aid of mercury; ſince, if they do ſo, they cannot in reality be ſyphilitic. This aſſertion, however, is by no means eſtabliſhed; and from the obſervations publiſhed by Pearſon, and other writers, on the effects of different remedies on the diſeaſe, we are to conclude that it is erroneous. The remarks, which we have quoted above, tend to ſhew that, even under the mere adminiſtration of bark, venereal buboes and ſyphilitic ulcers in the throat may ſometimes be healed. The teſtimony of Mr. Pearſon alſo confirms, that the muriatic and ſulphuric acids will improve venereal ſores, and reſtrain for a time the progreſs of the diſeaſe. The committee at the Ecole de Médicine, we find, announce that ſome few cures were effected by oxygenated lard and nitric lemonade. Theſe ſtatements, joined with the large body of reſpectable evidence from ſeveral other quarters already ſpecified, cannot fail to induce a ſuſpicion, that many medicines, beſides mercury, have a certain degree of power in reſiſting the ravages of the venereal diſeaſe; and that even ſyphilitic buboes and ulcers will ſometimes recede, look better, and heal, without mercury. We do not wiſh to inſinuate, that theſe things are deciſively eſtabliſhed; the diagnoſis of true venereal complaints being often ſo difficult, that men of great judgment and experience are liable to miſtakes.

Obſervations on the Treatment of particular Symptoms.

Treatment of Chancres.—Before the virus has been taken up by the abſorbents, a chancre is ſtrictly a local affection, quite unattended with any contamination of other parts. In this ſtate, there can be no doubt that there is a poſſibility of accompliſhing a cure by deſtroying with cauſtic the ſore, and adjacent part affected with the venereal action. Such an endeavour muſt be the more likely to ſucceed, when it is made while a chancre is ſmall, and in an incipient ſtate. The argentum nitratum is commonly employed for this purpoſe: but perhaps it might be preferable to uſe the kali purum and quicklime, which operate with more effect and quickneſs. Unfortunately, the period at which the abſorption of the virus begins is ſo uncertain, that the foregoing method is ſcarcely ever deſerving of ſuch implicit reliance, that mercury need not be employed at all. Small puſtules and ulcerated points on the penis are frequently deſtroyed with cauſtic, and a laſting cure is effected without mercury. Poſſibly ſome of theſe caſes may not be venereal; and when the practitioner infers that he has ſucceeded in preventing the abſorption of the virus, he may be deceived. In other inſtances, the endeavour to ſuperſede all occaſion for mercury, by extirpating a chancre with cauſtic, is only attended with a temporary appearance of ſucceſs; ulcerations of the tonſils, and other ſymptoms, denoting a general affection of the conſtitution, coming on ſoon after the healing of the ſore. Hence it is generally deemed prudent, not to be content with the attempt at extirpation with cauſtic, but to exhibit, at the ſame time, for a few weeks, the pil-hydrargyri. The mercury may ſometimes, indeed, be given unneceſſarily; but with its exhibition, and the cauſtic, the patient has a double chance of ſecurity againſt the extenſion of the diſeaſe to his conſtitution.

We ſhall firſt conſider the topical application to chancres.

Mercurial ointments have been commonly uſed as dreſſings to chancres; but Mr. Hunter was of opinion, that if the mercury were joined with watery ſubſtances, inſtead of oily ones, the application, by mixing with the matter, would be continued longer to the ſore, and would prove more effectual. This, he obſerves, is one advantage, which poultices have over common dreſſings. He has often uſed mercury rubbed down with ſome conſerve inſtead of ointment, and it anſwered extremely well. Calomel uſed in the ſame way, and alſo the other preparations of mercury mixed with mucilage, or honey, anſwer the ſame purpoſe. Such dreſſings, according to Mr. Hunter, will effect a cure in caſes which are truly venereal, and free from other morbid tendencies.

Some chancres are indolent, and require a little warm balſam or red precipitate to be joined with the mercurial dreſſing. Mr. Hunter ſays, that calomel mixed with ſalve is more active than common mercurial ointment, and is attended with better effects, when the caſe requires ſtimulants.

Solutions of blue vitriol, verdigris, calomel, &c. have been recommended. But Mr. Hunter very judiciouſly obſerves,

ſerves, that, as all theſe applications are only of ſervice in remedying any peculiar diſpoſition of the parts, as they have no ſpecific power over the venereal poiſon, and as ſuch diſpoſitions are innumerable, it is almoſt impoſſible to ſay what applications will be effectual in every inſtance. Some kinds of dreſſings will anſwer in one ſtate of the ſore; ſome in another. The parts affected are often found extremely irritable, in which circumſtance the mercury ſhould be mixed with opium or preparations of lead.

Mr. Hunter was an advocate for changing the dreſſings very often, becauſe the matter ſeparates them from the ſore, ſo as to diminiſh their effects. He ſtates, that changing the applications thrice a day, will not be found too often, particularly when they are in the form of an ointment.

When the venereal nature of a chancre is removed, the ſore frequently becomes ſtationary, in which caſe Mr. Hunter obſerves, that new diſpoſitious have been acquired, and the quantity of diſeaſe in the part has been increaſed. When chancres are only ſtationary, Mr. Hunter ſays, they may often be cured, by touching them ſlightly with the lunar cauſtic. No cicatrization, in this caſe, ſeems poſſible, till the contaminated ſurface, or the new fleſh, which grows on that ſurface, has either been deſtroyed or altered. It is often ſurpriſing, how quickly the ſores heal up, after being touched with the application.

At the ſame time that topical applications are made to chancres, mercury muſt be internally exhibited, both with a view of curing theſe ulcers, and preventing a lues venerea. Mr. Hunter believed, that the venereal diſpoſition of the chancre would hardly ever withſtand both local and internal mercurials.

When local applications cannot eaſily be made to chancres, as in caſes of phymoſis, there is a ſtill greater neceſſity for giving mercury internally, by which means, the cure may in the end be effected.

Mercury ſhould always be given internally in every caſe of chancre, let it be ever ſo ſlight, and even when the ſore has been deſtroyed on its very firſt appearance. The remedy ſhould always be exhibited the whole time of the cure, and continued ſome time after the chancre has healed; for, ſays Mr. Hunter, as there are, perhaps, few chancres without abſorption of the matter, it becomes abſolutely neceſſary to give mercury to act internally, in order to hinder the venereal diſpoſition from forming. How much mercury ſhould be thrown into the conſtitution in the cure of a chancre, with a view of keeping the ſyſtem from being affected, cannot eaſily be determined, as there is no diſeaſe actually formed, by which we can be guided. Mr. Hunter ſtates, that the quantity muſt in general be proportioned to the ſize, number, and duration of the chancres; or, in other words, proportioned to the opportunity, which there has been given for abſorption.

The mercury, which is exhibited to act internally, may be conveyed into the ſyſtem, either by the ſkin, or ſtomach, according to circumſtances, and it ſhould be ſo taken, as to produce a ſlight affection of the mouth.

Mr. Hunter next remarks, that when the ſore has put on an healthy look, when the hard baſis has become ſoft, and the ulcer has ſkinned over in a favourable manner, it may be regarded as cured.

The ſame diſtinguiſhed writer notices, however, that in very large chancres, it may not always be neceſſary to continue the application of mercury, either for external or internal action, till the ſore is healed, for the venereal action is juſt as ſoon deſtroyed in a large chancre, as it is in a ſmall one, ſince every part of the ſore is equally affected by the medicine, and, of courſe, cured with equal expedition. But, in regard to cicatrization, circumſtances are different, becauſe a large ſore is longer than a ſmall one, in becoming covered with ſkin. Hence Mr. Hunter very juſtly explains, that a large chancre may be deprived of its venereal action long before it has healed; while, on the other hand, a ſmall one may heal before the ſyphilitic affection has been deſtroyed. In the latter caſe, this gentleman repreſents it as moſt prudent, both on account of the chancre and conſtitution, to continue the employment of mercury a little while after the ſore has healed.

Mr. Hunter, in the valuable work which he has left on the preſent ſubject, takes notice of ſloughs, which occur in the tonſils, from the effect of mercury on the throat, and are apt to be miſtaken for venereal complaints. He alſo mentions, that ſometimes, when the original chancre has been doing well, and been nearly healed, he has ſeen new ſores break out on the prepuce, near the firſt, and aſſume all the appearance of chancres.

When, in the treatment of chancres, a bubo ariſes, while the conſtitution is loaded with a ſufficient quantity of mercury to cure ſuch ſores, which medicine has alſo been rubbed into the lower extremity, on the ſame ſide as the bubo, Mr. Hunter ſuſpected, that the ſwelling in the groin is not venereal, but is produced by the mercury. In theſe caſes, he always preferred conveying mercury into the ſyſtem in ſome other manner.

With reſpect to the treatment of chancres in women, ſince it is difficult to keep dreſſings on the parts, Mr. Hunter adviſes the ſores to be frequently waſhed with ſome mercurial ſolution, and ſpeaks of one made with corroſive ſublimate, as perhaps being the beſt, ſince it will act as a ſpecific, and ſtimulant alſo, when this is requiſite. When the chancres, however, are irritable, they are to be treated in the ſame manner, as ſimilar complaints in men. When the ſores extend into the vagina, this paſſage muſt be kept from becoming conſtricted, or cloſed, by the introduction of lint.

Sometimes, after a chancre and all venereal diſeaſe are cured, the prepuce continues thickened and elongated, ſo that the glans cannot be uncovered. Perhaps, the caſe is often without remedy. Mr. Hunter, however, very properly recommends trying every poſſible means, and he informs us, that the ſteam of warm water, hemlock fomentations, and cinnabar fumigations, are frequently of ſingular ſervice.

When the thickening and enlargement of the prepuce cannot be removed by applications, all the portion, anterior to the glans penis, may be cut away. See PHYMOSIS.

Mr. Hunter has very ably explained, that chancres, both in men and women, often acquire, during the treatment, new diſpoſitions, which are of various kinds, ſome retarding the cure, and leaving the parts in an indolent thickened ſtate, after the cure is accompliſhed. In other inſtances, a new diſpoſition ariſes, which utterly prevents the parts from healing, and often produces a much worſe diſeaſe, than that from which it originated. Such new diſpoſitions may lead to the growth of tumours. They are more frequent in men than women, and generally occur only when the inflammation has been violent from ſome peculiarity of the parts, or conſtitution. They have ſometimes been conſidered as cancerous.

Among the diſeaſes in queſtion, Mr. Hunter notices thoſe continued, and often increaſed inflammations, ſuppurations, and ulcerations, which become diffuſed through the whole prepuce, and alſo along the common ſkin of the penis, which become of a purple hue, attended with ſuch a general thickening of the cellular membrane, as makes the whole organ appear conſiderably enlarged. The ſame writer obſerves, that the ulceration on the inſide of the prepuce will ſometimes increaſe, and run between the ſkin and the body of the penis, and eat holes through in different places, till the whole is reduced to a number of ragged ſores. The glans often ſhares the ſame fate, till more or leſs of it is gone. Frequently, the urethra in this ſituation is wholly deſtroyed by ulceration, and the urine is diſcharged ſome way farther back. The ulceration, if unchecked, at length deſtroys all the parts. In this acute caſe, prompt relief is demanded; but often the proper mode of treatment cannot be at once determined, owing to our ignorance, in reſpect to the exact nature of the peculiar cauſe of the diſeaſe. Mr. Hunter ſtates, that the decoction of ſarſaparilla is often of ſervice, when given in large quantities, and that he has known the German diet-drink effect a cure, after every other remedy had failed.

Mr. Hunter alſo ſtates, that the extract of hemlock is ſometimes of ſervice, and that he has known ſea-bathing effect a perfect cure.

Sometimes, when ſuch ſores are healing, it becomes neceſſary to keep the orifice of the urethra from cloſing, by the introduction of a bougie.

Sometimes, after a chancre has healed, the cicatrix breaks out again, and puts on the appearances of the preceding ſore. Occaſionally, ſimilar diſeaſes break out in different places from that of the cicatrix. Mr. Hunter repreſents, that they differ from a chancre in generally not ſpreading ſo faſt, nor ſo far; in not being ſo painful, nor ſo much inflamed; in not having ſuch hard baſes, as venereal ſores have; and in not producing buboes. This writer was of opinion, that they were not venereal. They are very apt to recur.

Mr. Hunter does not ſpecify any particular mode of cure for all theſe caſes; but he mentions one inſtance, which ſeemed to be cured by giving forty drops of the lixivium ſaponarium, every evening and morning, in a baſin of broth; and he adverts to another caſe, which was permanently cured by ſea-bathing.

In ſome inſtances, after a chancre has healed, the parts, as Mr. Hunter remarks, do not ulcerate; but appear to become thickened and indurated. Both the glans and prepuce ſeem to ſwell, ſo as to form on the end of the penis a tumour, or excreſcence, ſhaped very much like a cauliflower, and, when cut into, ſhewing radii, running from its baſe, or origin, towards the external ſurface. It is extremely indolent. It is not always a conſequence of the venereal diſeaſe; for Mr. Hunter has ſeen it ariſe ſpontaneouſly.

No medicine ſeems to be at all likely to cure the diſeaſe: the only ſucceſsful means is to amputate a conſiderable part of the penis, and then to keep a proper catheter introduced into the urethra.

Warts.—Chancres often induce a diſpoſition to the formation of warts on the penis. We have in a former column ſtated our belief, that they are not venereal, though ſometimes curable by mercury. Hunter ſeems to think them not ſyphilitic, and we never have ſeen any which could not be cured without mercury, and this without the continuance of the original diſeaſe in any other form.'

Theſe ſubſtances are excreſcences from the body, they are not to be conſidered as truly a part of the animal, not being endowed with the common, or natural animal powers. Many trifling circumſtances make them decay. An inflammation of the ſound parts round the wart, or ſtimuli applied to its ſurface, will often make it die. Electricity will alſo induce an action in ſuch excreſcences, which they are not able to ſupport; an inflammation is excited round them, and they drop off.

From this account, we muſt perceive, according to Mr. Hunter, that the knife and eſcharotics are not always neceſſary, although theſe modes will act more quickly than any other, eſpecially when the neck of the wart is ſmall. When ſuch is the form of the excreſcence, perhaps a pair of ſciſſars is the beſt inſtrument; but, ſays the above diſtinguiſhed writer, when cutting inſtruments of any kind are horrible to the patient, a ſilk thread, tied round the neck of the wart, will do very well. However, whichever plan is adopted, it is in general neceſſary to touch with cauſtic the baſe of the little tumour, after this has ſeparated.

Mr. Hunter remarks, that eſcharotics act upon warts in two different ways, *viz.* by deadening a part, and ſtimulating the remainder, ſo that, by the application of eſcharotic after eſcharotic, the whole excreſcence decays moderately faſt; and it is ſeldom neceſſary to deſtroy them down to the very root, which is often thrown off. This, however, is not always the caſe, and the wart grows again, in which circumſtance, it is proper to let the cauſtic deſtroy even the root itſelf.

The kali purum cum calce vivâ, lunar cauſtic, and blue vitriol, are all proper applications. But one of the beſt ſtimulants is the ærugo æris and powder of ſavin-leaves, mixed together.

Treatment of Buboes.—When a bubo is certainly a venereal one, and only in an inflamed ſtate, an attempt is to be made to reſolve the ſwelling. The propriety of the attempt, however, depends on the progreſs which the diſeaſe has made. If the bubo be very large, and ſuppuration appears to be near at hand, reſolution is not likely to be effected. When ſuppuration has already taken place, Mr. Hunter much doubted the probability of any ſucceſs attending the endeavour, which now might poſſibly only retard the ſuppuration, and protract the cure.

The reſolution of theſe inflammations, ſays Mr. Hunter, depends principally on mercury, and almoſt abſolutely on the quantity which can be made to paſs through them. When ſuppuration has taken place, the cure alſo depends on the ſame circumſtances.

The quantity of mercury, which can be made to paſs through a bubo, is repreſented by Mr. Hunter as depending principally on the quantity of external ſurface for abſorption beyond the bubo.

The mercury is to be applied to ſuch ſurfaces as allow the remedy, when abſorbed, to paſs through the diſeaſed gland. In this manner, the diſeaſe in the groin is ſubdued, and the conſtitution is leſs liable to be contaminated.

However, Mr. Hunter accurately notices, that the ſituation of many buboes is ſuch, as not to have much ſurface for abſorption beyond them; for inſtance, the buboes on the body of the penis ariſing from chancres on the glands, or prepuce.

When the bubo is in the groin, Mr. Hunter recommends ſurgeons to pay attention to whether the ſwelling is in the upper part of the thigh and groin, on the lower part of the belly, before Poupart's ligament, or near the pubes. When the buboes are ſituated on the body of the penis, the abſorbents leading directly from the ſeat of abſorption are themſelves diſeaſed. When the bubo is in the groin, and at the upper part of the thigh, we may conclude that the lymphatics, both from the penis and thigh, run to the affected gland. When the bubo is high up, or on the lower part of the belly, before Poupart's ligament, probably the abſorbents, which ariſe from about the groin, lower part of the belly and pubes, paſs through the bubo. When the bubo is far forward, the abſorbents of the penis and ſkin about the pubes paſs through the ſwelling. Mr. Hunter contends, that the knowledge of theſe circumſtances is very neceſſary, in order to apply mercury in the moſt advantageous ſituations.

The utility of rubbing the mercury into ſurfaces, the abſorbents of which lead through the bubo, muſt be obvious, when it is conſidered, that the medicine cannot paſs to the common circulation without going through the diſeaſed parts; that it muſt promote the cure, as it paſſes through them; and that it alſo prevents the matter, which has already paſſed, and is ſtill continuing to paſs into the conſtitution, from acting there. Thus the bubo is cured, and the conſtitution, at the ſame time, preſerved.

Mercury alone, however, is not always capable of effecting the cure of buboes.

When the inflammation riſes very high, bleeding, purging, and fomenting, are generally recommended. When the inflammation was eryſipelatous, Mr. Hunter had a high opinion of bark; and when it was ſcrofulous, he uſed to recommend hemlock, and poultices made with ſea-water.

The ſame eminent writer alſo takes notice of the fact of emetics ſometimes occaſioning the abſorption of buboes, even after they contain matter.

1. *Reſolution of the Inflammation of the Abſorbents on the Penis.*—Though there is not ſurface enough beyond the bubo, for rubbing-in a ſufficient quantity of mercury, to prevent the effects of abſorption, Mr. Hunter ſtill adviſes this ſurface to be kept conſtantly covered with mercurial ointment. In conſequence of the ſurface in queſtion being ſo ſmall, more mercury muſt alſo be conveyed into the ſyſtem by the mouth, or frictions on ſome other part. Mr. Hunter obſerves, that this is neceſſary, both in order to prevent a lues venerea, and to cure the parts themſelves. The quantity of mercury muſt be regulated by the appearances of the original complaint, and the readineſs with which the diſeaſe gives way. The ſame method, he adds, is to be followed in women, and the ointment ſhould be kept continually applied to the inſide and outſide of the labia.

2. *Reſolution of Buboes in the Groin.*—The inflammation of the abſorbent glands is to be treated on the ſame principle as that of the veſſels. In the firſt caſe, however, we are able to make a larger quantity of mercury paſs through the diſeaſed parts. When the bubo is in the groin, the mercurial ointment is to be rubbed on the thigh. This ſurface, as Mr. Hunter remarks, will in general abſorb as much mercury as will be ſufficient to reſolve the bubo, and preſerve the conſtitution from being contaminated; but when reſolution does not readily take place, the ſame author adviſes us to increaſe the ſurface of friction, by rubbing the ointment upon the leg.

When the bubo is on the lower part of the belly, the ointment ſhould be rubbed alſo on the penis, ſcrotum, and belly. The ſame plan ſhould be followed when the bubo is ſtill more forward.

Mr. Hunter ſtates, that when the bubo gives way, the mercurial frictions muſt be continued, till it has entirely ſubſided, and, perhaps, longer, on account of the chancre, which may not yield ſo ſoon as the bubo. After the bubo has ſuppurated, Mr. Hunter is doubtful, whether rubbing-in mercury is uſeful, or not.

3. *Reſolution of Buboes in Women.*—When the ſwellings are ſituated between the labia and thigh, Mr. Hunter recommends the mercurial ointment to be rubbed-in all about the anus and buttock, from which parts the abſorbents probably run through the ſeat of the diſeaſes. When the buboes are in the round ligaments, the ſurface for abſorption will not be large enough, and more mercury muſt be internally given, or rubbed into other ſurfaces.

When the bubo is in one of the inguinal glands, the ſame plan is to be adopted as in the ſame caſe in men.

4. *Buboes in unuſual Situations.*—When buboes form in the arm, or arm-pit, in conſequence of the abſorption of venereal matter from wounds on the hands, or fingers, mercurial ointment ſhould be rubbed on the arm and fore-arm. Mr. Hunter adds, however, that this ſurface may not be ſufficient, ſo that it may be proper to convey more mercury into the ſyſtem in other ways. He ſtates, that he has ſeen a true venereal chancre on the middle of the lower lip, attended with a bubo, on each ſide of the neck, under the lower jaw, cloſe to the maxillary gland. The ſwellings were reſolved by applying mercurial ointment to them, and the chin and lower lip.

5. *Quantity of Mercury neceſſary for the Reſolution of a Bubo.*—Mr. Hunter obſerves, that the quantity of mercury neceſſary for the reſolution of a bubo, muſt be proportioned to the obſtinacy of the complaint; but that care muſt be taken not to extend the employment of the medicine ſo far as to produce certain effects on the conſtitution. When the bubo is in a ſituation which admits of a large quantity of mercury being rubbed in, ſo as to paſs through the ſwelling, and when the complaint readily yields to the uſe of half a dram of mercurial ointment every night, the mouth not becoming ſore, or at moſt only tender, the above author thinks it ſufficient to purſue this courſe, till the gland is reduced to its natural ſize. In this manner, the conſtitution will probably be ſafe, provided the chancre, which may have cauſed the bubo, heals at the ſame time. When the mouth is not affected in ſix or eight days, and the gland does not readily reſolve, then two ſcruples, or a dram, may be applied every night; and, continues Mr. Hunter, if there ſhould ſtill be no amendment, even more muſt be rubbed in. In ſhort (ſays he) if the reduction is obſtinate, the mercury muſt be puſhed as far as can be done without a ſalivation.

When there is a bubo on each ſide, ſo much mercury cannot be made to paſs through each, as the conſtitution in general will not bear this method. However, Mr. Hunter ſanctions the plan of minding the ſoreneſs of the mouth leſs in this kind of caſe; though, he adds, that it is better to let the buboes proceed to ſuppuration, than to load the ſyſtem with too much mercury.

When the ſituation of buboes will not allow an adequate quantity of abſorbed mercury to paſs through them, the frictions muſt be continued in order to affect the conſtitution; but, according to Mr. Hunter, more mercury in this caſe will be requiſite, than when the remedy can be made to paſs directly through the diſeaſed gland.

Many buboes remain ſwollen, without either coming to reſolution, or ſuppuration; and, notwithſtanding every attempt to promote theſe changes, the glands become hard and ſcirrhous. Mr. Hunter conceived, that caſes of this ſort are either ſcrofulous at firſt, or become ſo as ſoon as the venereal diſpoſition is removed. He adviſes the uſe of hemlock, ſea-water poultices, and ſea-bathing.

6. *Treatment of Buboes which ſuppurate.*—The ſuppuration of buboes frequently cannot be prevented by any known means. They are then to be treated, in ſome reſpects, like any other abſceſs. Before opening buboes, Mr. Hunter conceived it was advantageous to let the ſkin become as thin as poſſible, as a large opening would then become unneceſſary, and no meaſures would be requiſite for keeping the ſkin from cloſing, before the bottom of the ſore had healed.

Mr. Hunter thinks it doubtful, whether the application of mercury ſhould be continued through the whole ſuppuration. He was inclined to continue it; but in a ſmaller quantity.

There has been much diſpute, whether a bubo ſhould be opened, or allowed to burſt of itſelf, and whether the opening ſhould be made with a cutting inſtrument, or cauſtic. On this ſubject, Mr. Hunter remarks, that there is no peculiarity in a venereal abſceſs to make one practice more eligible than another. The ſurgeon, he ſays, ſhould in ſome degree be guided by the patient. Some patients are afraid of cauſtics; others, of cutting inſtruments. But when the ſurgeon has the choice, Mr. Hunter expreſſes a preference to opening the bubo with a lancet, in which method no ſkin is loſt. But, he obſerves, that when a bubo is very large, and there will be a great deal of looſe ſkin, after the diſcharge of the matter, he thinks that cauſtic may, perhaps, be better, as it will deſtroy ſome of the redundant ſkin, and occaſion leſs inflammation than what is cauſed by an inciſion. The kali purum, with the calx viva, is the cauſtic commonly employed.

After the bubo has been opened, ſurgeons uſually poultice it as long as the diſcharge and inflammation are conſiderable, and then they employ dreſſings, which muſt be of ſuch a quality, as numerous undeſcribable circumſtances may indicate. The uſe of mercury, in the mean while, is to be continued, both to make the bubo heal, and prevent the bad effects which might otherwiſe ariſe from the matter continually abſorbed. The mercury ſhould alſo be ſo rubbed in, as to paſs, if poſſible, through the diſeaſed groin.

The mercurial courſe is to be purſued till the ſore is no longer venereal. But, in general, ſince this point is difficult to aſcertain, the mercury muſt be given till the part has healed, and even ſomewhat longer, when the bubo has healed very quickly; for the conſtitution is afterwards very apt to become contaminated.

However, mercury is not to be continued thus long in all caſes; for, as Mr. Hunter explains, buboes often aſſume, beſides the venereal, other diſpoſitions, which mercury cannot cure; but will even exaſperate.

Conſequences of Buboes.—Sometimes the ſores, when they are loſing, or entirely deprived of the venereal diſpoſition, become changed into ulcers of another kind, and, moſt probably, of various kinds. How far it is a diſeaſe ariſing from a venereal taint, and the effects of a mercurial courſe jointly, ſays Mr. Hunter, is not certain. This writer ſuſpected, however, that the nature of the part, or conſtitution, had a principal ſhare in the malady.

Mr. Hunter obſerves, that ſuch diſeaſes make the cure of the venereal affection much more uncertain, becauſe, when the ſore becomes ſtationary, or the mercury begins to diſagree, we are ready to ſuſpect that the virus is gone; but this is not always the caſe. Perhaps the action of the venereal poiſon is only ſuſpended, and will commence again as ſoon as the other diſeaſe ceaſes.

In theſe caſes, Mr. Hunter recommends attacking the predominant diſeaſe; but he allows there is difficulty in aſcertaining its nature, and finding out whether it is venereal, or not.

The ſame author alſo acquaints us, that he has ſeen ſome buboes exceedingly painful and tender to almoſt every thing that touched them, and the more mild the dreſſings were, the more painful the parts became.

In ſome inſtances, the ſkin only ſeems to become diſeaſed. The ulceration ſpreads to the ſurrounding integuments, while a new ſkin forms in the centre, and keeps pace with the ulceration, ſo that an irregular ſore, which Mr. Hunter compares with a worm-eaten groove, is formed all round. It appears only to have the power of contaminating the parts which have not yet been affected; and thoſe which have readily healed.

When buboes become ſtationary, and ſeem little inclined to ſpread, attended with a ſinus or two, hemlock, joined with bark, is, according to Mr. Hunter, the medicine moſt frequently ſerviceable. It is beſt to uſe it both externally and internally. The ſame author alſo ſpeaks favourably of ſarſaparilla, ſea-bathing, and ſea-water poultices. He ſtates, that at the Lock Hoſpital, gold-refiners' water has been found a uſeful application; that, in ſome caſes, drinking large quantities of orange-juice, and in others taking mezereon, have been found ſerviceable.

Treatment of ſecondary Symptoms.—Before treating of this ſubject, it may be as well to recapitulate a few of the leading points in Mr. Hunter's doctrine.

1. Syphilitic matter, after being abſorbed into the ſyſtem, circulates with the blood, and is thrown out by the common emunctories; but in its progreſs it may contaminate other parts of the body, and give them a diſpoſition to diſeaſe.

2. When this diſpoſition is given, the diſeaſed action does not follow till a certain time, which varies according to the conſtitution and other circumſtances; but never happens while the conſtitution is under a mercurial irritation.

3. When the diſpoſition has taken place, the action may be ſuſpended by mercury; but the diſpoſition will remain, and the action ſhew itſelf at ſome period after the mercurial irritation has ceaſed.

4. When the action has begun in an order of parts it may be cured, and will not return in the part, or that order of parts from the ſame ſtock of infection.

5. But the diſeaſed action may take place in another order of parts, if that other order has been contaminated; and, in this order, it muſt be treated as in the former.

6. When the diſeaſed action has taken place and been cured in the part firſt infected, in the throat and fauces, the ſkin, and the bones or perioſteum, the ſubject may be ſaid to be free from the diſeaſe, as far as our knowledge has hitherto traced it.

7. The uſual time of the ſkin or fauces taking on the diſeaſed action is, on a medium, ſix weeks after the mercurial irritation that cured the firſt ſymptoms has ſubdivided; and in the bones about twice that time.

8. Whatever doubtful appearances may ariſe on the ſkin, throat, or bones, during the mercurial irritation, under which chancres, or buboes are giving way, they are certainly not venereal: and even if ſuch ſecondary ſymptoms appear after that mercurial irritation has ceaſed, but earlier than the period ſpecified in the preceding propoſition, they are to be regarded with doubt.

9. If no ſecondary ſymptoms appear for three months after the mercurial irritation has ceaſed, and the conſtitution has not in the mean time been occupied by any other diſeaſe, we have for the moſt part no reaſon to apprehend any thing in the ſkin or throat from that ſtock of infection.

Laſtly, there are uncommon inſtances, in which the ſecondary ſymptoms occur ſooner or later than the periods above ſtated. See Hunter's Treatiſe, and Adams on Morbid Poiſons, p. 159, 160.

The treatment of ſecondary ſymptoms conſiſts almoſt entirely of the judicious employment of mercury. Frictions with the ointment are generally the moſt preferable; but ſometimes the pill hydrarg. oxydi rubri, the ſolution of the oxymuriate, or the adminiſtration of mercury by fumigation (ſee FUMIGATION), may be proper and advantageous. The continuance of the mercurial courſe muſt always be ſuſpended, when the effects produced are attended with too much violence or diſorder. Opium may be given to leſſen and check the diarrhœa, which ſometimes ariſes from mercury, and both weakens the patient and diminiſhes the ſpecific action of that mineral on the diſtemper. Sometimes other medicines will be uſeful, either given after the mercury is done with, while it is omitted for a time, or even in conjunction with it. This may be ſaid of bark, cicuta, opium, ſarſaparilla, and the diet-drinks already ſpecified. Whatever doubts may prevail reſpecting the antivenereal qualities of nitric acid, none remain with regard to its utility in meliorating the ſtate of many complaints, which may exiſt after the ſyphilitic action has been entirely ſubdued by a previous exhibition of mercury. But in our general obſervations we have already been ſo full in our directions for the management of a mercurial courſe, and in our account of the effects of other medicines in caſes of ſyphilis, that it would be the moſt ſuperfluous prolixity to enlarge on this ſubject.

There is one queſtion, however, that preſents itſelf as deſerving conſideration, namely, how long a mercurial courſe ought to be continued? We find that it was one of Mr. Hunter's opinions, that when venereal matter is abſorbed, it may produce in parts a diſpoſition to the diſeaſe, or, in other words, a ſtate of contamination, which, though it might have been hindered by the timely effects of mercury, and may now be kept from going into action as long as the ſyſtem is under the influence of mercury, yet cannot be cured, but muſt ſome time or another proceed to action, or a ſtate of palpable diſeaſe. In this condition alone it is curable. We obſerve, however, that Mr. Hunter, in his practice, is not altogether regulated by this principle; for in his directions for the cure of a chancre, he recommends mercury to be followed up ſome time after the ſore is cured, which medicine being ſuppoſed not to be capable of curing the diſpoſition that may be formed, (and if formed at all, muſt have formed ere this,) the method, according to reaſon, can be of no ſervice. We cannot pretend to deliver an opinion whether the practice is poſitively right or the theory wrong. One thing or the other muſt be the caſe. But it is our duty to ſtate that the generality of ſurgeons think it prudent to go on with mercury a certain time after ordinary chancres are healed. But in the treatment of ſecondary ſymptoms we believe the perſeverance in mercury, after all palpable ſyphilitic miſchief is removed, is utterly wrong and unneceſſary. In other reſpects, the mercurial courſe for the relief of ſecondary ſymptoms is to be conducted exactly in the ſame manner as in caſes of chancre or bubo, and according to the directions given in our general obſervations. Should the ſecondary ſymptoms in the throat, ſkin, mouth, or noſe, have taken place and been cured by mercury, we may aſſure the patient that whatever appearances may now preſent themſelves in theſe parts, the complaints cannot be really ſyphilitic. Therefore the continuance of mercury is not indicated. But though we may venture to predict that the diſeaſe will not recur in this firſt order of parts, we cannot promiſe as much with reſpect to the ſecond order, *viz.* the bones, perioſteum, and tendons. Whether theſe have contracted the diſpoſition, or, in other words, are contaminated or not, can never be known *à priori.* If they have contracted the diſpoſition, this cannot be cured by mercury, but will, ſome time or other, take on the ſyphilitic action, or, in other terms, fall into a ſtate of obvious and palpable diſeaſe. It is only in this laſt condition that mercury can exert its beneficial power in effecting a permanent cure. Were this medicine given under the idea of preventing ſyphilitic miſchief, it might indeed delay the coming on of the complaints, but after the diſpoſition has been formed, they muſt ſooner or later follow. Mercury was ſuppoſed by Hunter to be ſometimes capable of preventing the diſpoſition from being formed at all, if exhibited in an early ſtage of a chancre, before the virus has been abſorbed. But as much abſorption, and the conſequent diſpoſition for the diſeaſe in certain parts take place at an early period of the caſe, all perſeverance in mercury for the prevention of any more ſecondary ſymptoms is, according to the Hunterian tenets, altogether fruitleſs. If the ſoft parts or firſt order have been cured, we cannot conſider our patient ſafe, reſpecting the bones, perioſteum, and tendons, or ſecond order, till a medium of at leaſt ſix weeks after the laſt mercurial irritation has ceaſed. Of this the patient ſhould always be warned. The affections of this ſecond order of parts generally conſiſt of nodes and pains. But it is not every ſwelling or pain in a ſuſpected bone that is really venereal. Mercury itſelf will ſometimes bring on painful affections and enlargements of the bones. Even when nodes are ſyphilitic, it often happens—that no continuance nor quantity of mercury will totally remove the ſwelling. Such medicine is only to be continued till we have reaſon to infer all ſyphilitic action in the part is ſubdued, Whatever degree of thickening or enlargement may now remain is only of a common nature, does not demand mercury, and frequently admits of being materially leſſened, or even entirely removed, by bliſters, if care is taken to keep up a diſcharge from the excoriated ſurface with the ſavine cerate.

Some other caſes, connected with the ſubject of lues venerea, will be conſidered in the articles PHIMOSIS and PARAPHIMOSIS. See alſo GLEET, GONORRHŒA, &c.

LUESIA, in *Geography*, a town of Spain, in the province of Aragon; 20 miles S.W. of Jaca.

LUFF, a ſea-term, the ſame with *loof.*

LUFFA, in *Botany*, the Arabic name of an herb of the Cucumber family, *Momordica Luffa*, Linn. Sp. Pl. 1433. Veſling. Ægypt. 48. t. 50, 51. Cavanilles, in his *Icones*, v. 1. 7. t. 9, 10, has applied it generically to a plant called by him *Luffa fœtida*, a native of the Eaſt Indies, with which he thinks it probable that the above *Momordica* may agree in generic characters. Willdenow has adopted this *Luffa*, in his Sp. Pl. v. 4. 383. How far the difference in its ſtamens, whoſe anthers are all ſeparate, and which are accompanied by five abortive filaments, may ſerve to keep it diſtinct, we very much doubt. As to the fruit, it appears nearly to agree with *Momordica Operculata.*

LUG, in *Agriculture*, a long meaſure of land, the ſame with pole or perch, ſixteen feet and a half. In Glouceſterſhire, it however ſignifies a land-meaſure, of ſix yards, or a rod, pole, or perch of ſix yards. It is a meaſure by which ditching and other ſimilar operations are performed in that diſtrict. This term is likewiſe applied to the ſtick by which the work is meaſured. It is ſometimes called *log.*

LUG-*a-Leaf*, a name uſed in ſome parts of England for the *rhomboides* of Rondeletius, and the *rhombus non aculeatus ſquamoſus* of Willughby.

We have it on our own ſhores; and the Corniſh people, who frequently catch it, call it the *lug-a-leaf.* See PLEURONECTES *Plateſſa.*

LUG-*ſail*, in *Sea Language*, is a ſquare ſail, hoiſted occaſionally on the maſt of a boat or ſmall veſſel, upon a yard which hangs nearly at a right angle with the maſt. Theſe are chiefly uſed in the *barca longas*, navigated by the Spaniards in the Mediterranean.

LUGA, in *Geography*, a town of Ruſſia, in the government of Peterſburgh, on a river of the ſame name; 80 miles S. of Peterſburg. N. lat. 58° 25′. E. long. 29° 30′.

LUGANO, or LAURS, a territory of Italy, ceded to the Swiſs cantons in 1513; it is environed by the diſtricts of

Mendris Lugarus, Bellinzona, and the duchy of Milan; it is fertile and populous, about eight leagues long and five broad, lying in N. lat. 46°, and is divided into quarters, containing 106 market towns and villages, and 53,000 inhabitants. This territory produces paſture, corn, fruit, and ſilk; olives are in great abundance. It is now ceded to Italy.—Alſo, the capital of the fore-mentioned bailiwic or diſtrict, which is a ſmall, tolerably built, trading town, delightfully ſituated round the curve of a bay, and backed by a ſucceſſion of hills, riſing in gentle ſwells to a conſiderable height; in front a bold mountain clothed with foreſt projects into the lake, of which a noble branch extends to its right and left. To that ſpot boats of various ſizes are continually paſſing and repaſſing, its baſe being perforated with *cantine*, or caverns, to which the inhabitants ſend their meat, and all ſorts of proviſion, where it is kept untainted for ſeven or eight days, and the wine preſerved with delicious coolneſs. The heats are moderated by the ſurrounding hills, and the cool breezes from the lake. It is no leſs ſheltered from the Alpine blaſts, which, chilled by the neighbouring ſnows, would otherwiſe deſtroy the temperature of this equal climate. Olive, almond, and all the ſouthern fruits ripen here to perfection. Lugano is the emporium of the greater part of the merchandiſe which paſſes from Italy over the St. Gothard, or the Bernardin. At the end of autumn, the Swiſs mountaineers bring down numerous herds of cattle for ſale, and return with leſs bulky commodities. The town contains about 8000 inhabitants; moſt of the houſes are built of tuf-ſtone; the reſidence of the capitano, or governor, is a low building; and on the walls are the arms of the twelve regent cantons. On an eminence above the town ſtands the principal church, remarkable only for the beautiful carvings in ſtone round the doors and roſe-window, and for the delicious proſpect from its towers. In the cloiſter of the Recollets is a capital picture attributed to Luvino; their church is handſome, and the ſkreen is ornamented with the paintings of the Paſſion by the ſame maſter. The palace of the Marquis de Riva contains a few good pictures; 16 miles N.W. of Como. N. lat. 45° 50′. E. long. 8° 53′. Coxe's Switzerland, vol. iii.

LUGANO, *Lake of*, a lake adjoining to the town above deſcribed, about 25 miles in length, and from two to four in breadth; its form is irregular, and bending into continued ſinuoſities. From Porto, a ſmall village, ſituated at its ſouthern extremity, an arm of the lake bends northward, and diſcharges itſelf into the Lago Maggiore, by means of the river Triſa. It is ſcarcely poſſible, ſays Mr. Coxe, to imagine a more perfect or greater variety of beauties than this noble piece of water affords. The vaſt overhanging woods, the bold precipices, the tranſparency of the water, unite to form a ſcenery in the higheſt degree luxuriant. This lake is about 190 feet perpendicular higher than the lake of Como and Lago Maggiore. The two laſt mentioned lakes are of the ſame level, and about 240 feet higher than the city of Milan. Coxe. See LAKE.

LUGARBEN, a town of Pruſſia, in Natangen; 36 miles S.E. of Konigſberg.

LUGAR-NUEVO, a town of Spain, in Valencia, on the coaſt; eight miles S. of Alicant.

LUGDE, or LUDE, a town of Weſtphalia, in the biſhopric of Paderborn, on the Emmer; 24 miles N.N.E. of Paderborn. N. lat. 51° 55′. E. long. 9° 18′.

LUGDUNUM, in *Ancient Geography*. See LYONS.

LUGDUNUM *Batavorum*. See LEYDEN.

LUGGS, the Engliſh name for a peculiar ſpecies of inſect, found in great plenty on the ſhores of Cornwall. It is of the nature of the *ſcolopendra*, and is called by Mr. Ray *vermis ſcolopendroides*. It grows to twelve inches long, and has inſtead of legs nineteen pair of ſtiff briſtles, all which ſtand toward the head part of the creature. The tail is at leaſt five inches long when full grown, and has no mark of them. Its body is rounded, and much reſembles the body of the common earthworm, and is of a fleſh-colour, or pale red. It has no forceps.

LUGMON, in *Natural Hiſtory*, a name given by the people of the Philippine iſlands to a ſpecies of turtle, the female of which has a tuft of red feathers, of a pale blood colour, on her breaſt, which have greatly the appearance of a wound, ſo much that any body would really be deceived.

LUGNAQUILLA, in *Geography*, mountains of Ireland, in the county of Wicklow.

LUGNY, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the diſtrict of Mâcon; 10 miles N. of Mâcon. The place contains 1133, and the canton 12,776 inhabitants, on a territory of 172½ kiliometres, in 19 communes.

LUGO, JOHN DE, in *Biography*, a learned Spaniſh Jeſuit and cardinal, was born at Madrid in 1583. He gave early proofs of his attachment to the introductory parts of learning, and was ſent to ſtudy the law at Salamanca, where he entered the ſociety of Jeſuits, thereby following the example of his brother, though contrary entirely to the wiſh of his father. Upon the death of the father, the two ſons divided a very large eſtate that had fallen to them among the Jeſuits of Seville and Salamanca. He became profeſſor of philoſophy at Medina del Campo, then profeſſor of divinity at Valladolid, and afterwards he filled the divinity chair at Rome. In 1643 he was raiſed to the dignity of cardinal by pope Urban VIII. without his knowledge, and he died at the age of ſeventy-ſeven, in the year 1660. He was the author of ſeven folio volumes, chiefly in theology and morals, of which a few tracts only have any degree of merit, ſuch as "De Virtute et Sacramento Penitentiæ," and "De Juſtitia et Jure." He is, however, particularly celebrated as being the perſon who brought the virtues of bark into notice, which he introduced into France in the year 1650, and which, under the name of "Cardinal Lugo's powder," he adminiſtered gratis to the poor, but obliged the rich to purchaſe with its weight in gold. Bayle.

LUGO, *Lucus Auguſti*, in *Geography*, a very ancient town of Spain, in the province of Galicia, which, in the time of the Romans, was the centre of one of thoſe juriſdictions that were named "Conventus." At preſent it is the ſee of a biſhop, ſuffragan to St. Jago, and worth 1550*l.* ſterling. It is ſituated on an eminence near the banks of the Minho, 13 leagues from its ſource. Here ſeveral councils have been held; and among others, one in 564 to regulate the limits of the biſhoprics of Galicia and Portugal. It is at moſt three miles in circumference: and the ſtreets are tolerably handſome and well paved. It has 12 ſquares, three fountains, and five gates. The walls are ancient, but in good repair. The city contains a cathedral, ſeveral churches and convents, the biſhop's palace, a college, a hoſpital, and an aſylum. The civil adminiſtration is compoſed of an alcalde major, a regidor, and ſeveral diſtrict alcaldes. The cathedral is a very ancient building of Gothic architecture, with a modern portal. Lugo is ſuppoſed to contain more than 4600 inhabitants. They work up wools in this town, but not enough to ſend any out of the country. In its territory is a number of thermal ſprings, temperate and boiling. Wheat, barley, rye, and maize, are produced in the environs; and many large flocks of ſheep are to be ſeen. The Minho ſupplies trout, ſalmon, and lampries. Lugo is diſtant from St. Jago 13 leagues. N. lat. 43° 2′. W. long. 7° 32′.—Alſo, a town of Italy, in the Veroneſe; eight miles N. of Verona. —Alſo, a town of Italy, in the Paduan; 10 miles E. of Padua.—Alſo, a town of Italy, in the department of the Lower Po; 15 miles S. of Ferrara.

LUGOS, a town of Hungary; 37 miles S.W. of Coloſvar.—Alſo, a town of Hungary, in the bannat of Temeſvar, on the Temes; 23 miles E. of Temeſvar.

LUGUBRE, *Fr.* in *Muſic,* a term which implies gloomy, melancholy, dejected.

LUHANGO, in *Geography,* a town of Sweden, in the province of Tavaſtland; 60 miles N.N.E. of Tavaſtland.

LÜHEA, in *Botany,* ſo named by Willdenow, in compliment, as we preſume, to F. K. Freyherr von der Lühe, who publiſhed at Vienna, in 1797, a German hymn to Flora. His poetry ought to be very fine, as we hope it is, to merit ſo magnificent a plant.—Willd. Sp. Pl. v. 4. 1434.—Claſs and order, *Polyadelphia Polyandria.* Nat. Ord. *Columniferæ,* Linn. *Malvaceæ,* Juſſ.

Gen. Ch. *Cal.* Perianth inferior, double; the *outer* of nine equal, linear leaves, channelled at the back; *inner* in five deep, lanceolate ſegments, internally ſmooth, naked, and coloured. *Cor.* Petals five, longer than the calyx, broad, roundiſh, wavy, crenate, veiny. Nectaries five, ſtalked, pencil-ſhaped, hairy. *Stam.* Filaments numerous, hairy, united into five ſets at their baſe; anthers incumbent, roundiſh, ſmooth. *Piſt.* Germen roundiſh, or conical, with five angles, hairy; ſtyle columnar, thick, ſhorter than the ſtamens, ſmooth upwards; ſtigma orbicular, broad, depreſſed, with ſeveral radiant furrows. *Peric.* Capſule of five cells. *Seeds* winged.

Eſſ. Ch. Calyx double; the outer of nine leaves; inner in five deep ſegments. Petals five. Nectaries five, pencil-ſhaped. Style one. Capſule of five cells. Seeds winged.

1. L. *ſpecioſa.* Willd. Nov. Act. Soc. Nat. Scrut. Berol. v. 3. 410. t. 5.—Native of lofty mountains in the Caraccas, from whence we have a ſpecimen, gathered by Dr. J. Mœrter, to whom, though we do not meet with his name, the Vienna gardens are indebted for many of the fineſt plants publiſhed by Jacquin. From him we learn what is mentioned above reſpecting the capſule and ſeeds, about which Profeſſor Willdenow had no information. We have had no opportunity of conſulting his original account in the memoirs of the Berlin ſociety, which is here cited on his own authority in his *Species Plantarum.*

This, the only known ſpecies, is a *tree,* 20 or 30 feet high, with alternate, round, brown *branches,* downy when young. *Leaves* alternate, on ſhort, thick, downy *ſtalks,* roundiſh-oblong, pointed, ſlightly heart-ſhaped and a little unequal at the baſe, three or four inches long, unequally and ſharply ſerrated; ſmooth and naked above; white with denſe ſtellated down, furniſhed with three prominent ribs, and numerous tranſverſe parallel veins, beneath. *Flowers* white, large and handſome, not many together, in downy, terminal, ſimple cluſters. The *calyx* and partial *ſtalks* are clothed with denſe pubeſcence, of a ruſty hue in the dried ſpecimen.—This plant is cloſely allied in habit and fruit to the *Pteroſpermum* of Schreber and Willdenow (*Pentapetes ſuberifolia* and *acerifolia* of Linnæus); the differences in their flowers however ſeem eſſential, eſpecially as the calyx of *Pteroſpermum* is ſimple.

LUHYNY, in *Geography,* a town of Ruſſian Poland; 24 miles W.S.W. of Owrucza.

LUICHEN, a city of China, in Quang-tong, ſituated in a fertile and pleaſant country, near the ſea. N. lat. 28° 58′. E. long. 110° 8′.

LUIDA, in *Botany,* Adanſon v. 2. 492, was ſo called by that writer after Mr. Edward Llwyd, the correſpondent of Ray, who is mentioned in his *Synopſis* as the diſcoverer of ſeveral moſſes and other plants in Wales. This ſuppoſed genus however will neither immortalize him, nor its whimſical author, being made up of various ſpecies of *Hypnum, Bryum, Splachnum,* &c. characteriſed by having ſome leaves triangular and ſome orbicular! Mr. Llwyd appears, by what Ray ſays of him, in the preface to the ſecond edition of his *Synopſis* and elſewhere, to deſerve more permanent commemoration.

LUIGI Rossi, in *Biography,* one of the earlieſt and moſt voluminous compoſers of cantatas in the ſeventeenth century. He is celebrated in 1640 by Pietro della Valle, in his letter to Guidiccioni, for his grave canzonette, particularly that which begins "Or che la notte del ſilenzio amica."

Many of his cantatas are preſerved in all the collections which include the muſic of the laſt century, particularly in the Brit. Muſ. Bibl. Harl. 1265 and 1273, and in Dr. Aldrich's Collection, Chriſt-church, Oxon.

His cantata, "La Fortuna," in the Muſeum collection, No. 1265, is of an immeaſurable length. The recitative, however, with formal cloſes, has pleaſing expreſſions in it, that ſtill live. No *da capo,* or ſign of reference, appears in his cantata, and he writes twice or three times over the ſame airs; a trouble which theſe expedients would have ſpared. He ſeems to have ſtarted ſeveral flimſy diviſions, which afterwards became common; and, indeed, it appears from his cantatas, that as ſoon as ſecular muſic had diveſted itſelf of the pedantry of perpetual canons, fugues, and multiplied parts, another vice crept into the art, by the frequent and exceſſive uſe of diviſions. Luigi, in ſongs for a ſingle voice, has ſome of this kind as long as thoſe in modern bravura airs.

In the Magliabecchi library at Florence, we found a ſcene of oratorio called "Giuſeppe Figlio di Giacobbe, opera ſpirituale fatta in muſica da Aloigi de Roſſi, Napolitano, in Roma." And under the name of *Roſſi* many of his compoſitions may be found in the muſeum.

Luigi, in his motets that are preſerved in the Chriſt-church collection, appears to have been as able to write *à cappella,* in many parts with learning, as with elegance in few.

LUIGNA, in *Geography,* a town of Spain, in Aſturias; 20 miles N.W. of Oviedo.

LUI-LUNG-TA. See Sechoo.

LUING, or Long Island, one of the ſmaller weſtern iſlands of Scotland, between Scarba and Kerrera.

LUINI, Bonetto, of Breſcia, in *Biography,* an opera ſinger in ſoprano, who had been in Ruſſia and other foreign countries, and acquired great wealth, but diſſipated great part of it by play. Yet, after loſing ten thouſand pounds in one night of the money which he had gained *con la ſua virtù,* he was ſtill ſaid, in Italy, to be very rich.

LUIS, St., in *Geography,* a town of South America, in the government of Buenos Ayres, and province of Cordova; 170 miles S.W. of Cordova. S. lat. 32° 10′. W. long. 67° 12′.—Alſo, a town of South America, in the province of Moyes; 72 miles N.W. of Trinidad.—Alſo, a miſſion of Spaniſh monks in New Albion; 10 miles N.E. of Punta el Eſteros.—Alſo, a town of New Navarre; 90 miles S. of Caſa Grande.

Luis *de la Paz, St.,* a town of Mexico, in the province of Mechoacan; 100 miles N. of Mechoacan. N. lat. 21° 50′. W. long. 102° 16′.

Luis *de Maranon, St.* See *St.* Felipe.

Luis *de Potoſi, St.*, a city of Mexico, in the province of Guaſteca, pleaſantly ſituated, and environed with rich gold mines. The town is handſome and well built, conſiderable in ſize, and populous. The ſtreets are ſtraight and neat, the churches magnificent; and the inhabitants, who are chiefly Indians, poſſeſſing all the conveniencies and comforts of life; 190 miles N.N.W. of Mexico. N. lat. 22° 25′. W. long. 103° 6′.

Luis *de Zacatecas*, a town of Mexico, capital of the province of Zacatecas, the ſee of a biſhop, and reſidence of a governor; 240 miles N.N.W. of Mexico. N. lat. 22° 50′. W. long. 103° 46′.

LUI-SHIN, in *Mythology*, the Jupiter of the Chineſe, or ſpirit that preſides over thunder. The figure of it has the wings, beak, and talons of an eagle. In his right hand he holds a mallet, to ſtrike the kettle-drums with which he is ſurrounded, whoſe noiſe is intended to convey the idea of thunder; while his left is filled with a volume of undulating lines, very much reſembling thoſe in the hands of ſome of the Grecian Jupiters, and evidently meant to convey the ſame idea, *viz.* that of the thunder-bolts, and lightning.

LUISIANA, in *Geography*, a diſtrict of Spain, in Andaluſia, three leagues from Ecija, ſettled in 1791 by a colony of Germans, who built houſes in an uniform plan, allotting to each houſe a portion of land, which conſtituted a village; but the houſes are already beginning to fall into ruin.

LUISINUS, Louis, in *Biography*, a phyſician, was born at Udina, in the ſtate of Venice, where he obtained conſiderable reputation about the middle of the ſixteenth century, and was not leſs diſtinguiſhed by his acquiſitions in literature, than by his medical ſkill. He was author of the following works: "Aphoriſmi Hippocratis hexametro carmine conſcripti," Venice, 1552; "De compeſcendis animi affectibus per moralem philoſophiam et medendi artem, Tractatus in tres Libros diviſus," Baſle, 1562; "Aphrodiſiacus, ſive de Lue Venerea, in duos Tomos bipartitus, continens omnia quæcumque hactenus de hac re ſunt ab omnibus Medicis conſcripta," Venice, 1566, folio. The firſt volume contained an account of the printed treatiſes on the lues up to that year; the ſecond, publiſhed the year following, comprehended principally the manuſcript works on the ſubject, which had not then been committed to the preſs. Eloy Dict. Hiſt. de la Médecine.

LUISNANSBERG, in *Geography*, a town of Sweden, in Weſtmanland; 48 miles N.W. of Stroemſholm.

LUJULA, in *Botany*, &c. See Oxalis *Acetoſella*.

LUK, in *Geography*, a town of Bohemia, in the circle of Saatz; 6 miles E. of Carlſbad.

LUKAU, a town of Moravia, in the circle of Znaym; eight miles W.N.W. of Znaym.

LUKAWETZ, a town of Bohemia, in the circle of Czaſlau; 28 miles S.W. of Czaſlau.

LUKE, St., in *Sacred Biography*, one of the evangeliſts, and the writer of the goſpel bearing his name, and alſo of the book of the Acts of the Apoſtles. Concerning his profeſſion and country, previouſly to his converſion to Chriſtianity, there is a difference of opinion among both ancient and modern authors. The firſt mention of him in the books of the New Teſtament occurs in his own hiſtory. (Acts, xvi. 10, 11.) When the apoſtle Paul was again, a ſecond time, in Greece, it appears, from Acts, xx. 1—6, that St. Luke was with him; and that he acccompanied Paul from Greece through Macedonia to Philippi, and went with him from thence to Troas. It further appears from the ſequel of the hiſtory in the Acts, that he accompanied the apoſtle to Jeruſalem, and remained with him there. When the apoſtle was ſent a priſoner from Cæſarea to Rome, Luke was in the ſame ſhip with him, and ſtaid with him at Rome during the whole interval of his two years' impriſonment in that city. Of this fact we have alſo collateral evidence from the epiſtles of St. Paul written at this time. (2 Tim. iv. 11. Philem. v. 24.) And if Luke the beloved phyſician, mentioned Col. iv. 14, be the evangeliſt, this paſſage affords additional proof of his being then with the apoſtle. Some have alſo ſuppoſed that he is the perſon mentioned 2 Cor. viii. 18, as "the brother, whoſe praiſe is in the goſpel throughout all the churches." Dr. Lardner, with his uſual induſtry and accuracy, has collected the teſtimonies of various ancient writers concerning the evangeliſt Luke; and from theſe he deduces ſeveral inferences that ſerve to ſettle his profeſſion and country, and to correct the miſtakes of other authors. The notion which ſome have entertained, that he was a painter, is without foundation, as it is not countenanced by ancient writers. The learned Grotius and J. Wetſtein have ſuggeſted, that he was a Syrian and a ſlave, either at Rome, or in Greece; and that having obtained his freedom, he returned to his native place, Antioch; where he became a Jewiſh proſelyte, and then a Chriſtian. This opinion is alſo rejected by our author; who obſerves, that the account given of this evangeliſt by Euſebius, and by Jerom after him, that he was a Syrian, and a native of Antioch, is not ſupported by the authority of Irenæus, Clement of Alexandria, Tertullian, or Origen, nor indeed by any other writer before Euſebius. Cave and Mill have intimated, that Luke was converted by Paul at Antioch; but it is alleged, on the other hand, that if Luke had been a Gentile, converted by Paul, he would have been always uncircumciſed, and unfit to be the companion of Paul. For the apoſtle would not have allowed the Greeks or Gentiles of Antioch, or any other place, to ſubmit to that rite. Beſides, no hints occur in the Acts, or in the epiſtle of St. Paul, that Luke was his convert. It has been doubted by ſeveral learned men, whether the evangeliſt Luke was a phyſician. Dr. Lardner allows, that the diſtinguiſhing character of "beloved phyſician" (Col. iv. 14.) has occaſioned a difficulty, which, however, he thinks, is not inſuperable; and he conceives it probable, that Luke the evangeliſt was by profeſſion a phyſician. That St. Luke was a Jew by birth, or at leaſt by religion, our author argues from his being a conſtant companion of Paul in many places, particularly at Jeruſalem. If he had been an uncircumciſed Gentile, ſome exceptions would have been made to him, which we do not find from St. Paul's epiſtles, or the Acts, to have been the caſe; and beſides, he follows the Jewiſh computations of times, ſuch as the paſſover, the pentecoſt, and the faſt. (See Acts, xii. 3. xx. 6. 16. xxvii. 9.) In this opinion, that St. Luke was a Jew, many learned and judicious moderns, as Mr. L. Baſnage and J. A. Fabricius, concur; and Dr. Lardner thinks, that it ought not to be queſtioned. Moreover, he was probably an early Jewiſh believer, ſoon after Chriſt's aſcenſion, if not a hearer of Chriſt, and one of the 70 diſciples. The moſt ancient writers ſpeak of Luke as a diſciple of the apoſtles. Some have reckoned him one of the Seventy, others have thought him to be Lucius, mentioned by St. Paul in the epiſtle to the Romans, and others have ſuppoſed, that he was one of the two diſciples that met Jeſus in the way to Emmaus. If Lucius be the evangeliſt Luke, which is an opinion adopted by ſeveral learned writers, we may conclude, that he was a Jew, and related to the apoſtle. We may know his character, and, in part, his hiſtory, from Acts, xi. 19—21, and xiii. 1—4. He was an early Jewiſh believer after Chriſt's aſcenſion, and together with others was very ſerviceable in preaching the goſpel, at an early period, to Jews and Gentiles out of Judea. And if the other diſciple, who accompanied Cleopas in the way to Emmaus, be Luke the evangeliſt, he was a diſciple and eye-witneſs of Jeſus Chriſt; though we do not allow him to be one of the 70. It appears further, that St. Luke was for a conſiderable time a conſtant companion of St. Paul; and that he was alſo acquainted with other apoſtles. It is probable, that St. Luke died a natural death; becauſe none of the moſt ancient writers, ſuch as Clement of Alexandria, Irenæus, Origen, Euſebius, and Jerom, ſay any thing of his martyrdom. Gaudentius, biſhop of Breſcia, about the year 387, obſerves, that in his time it was generally ſaid, that Luke and Andrew finiſhed their courſe at Patræ in Achaia, but without adding that it was by martyrdom: and if St. Luke be called a martyr, the appellation may be underſtood in a general ſenſe, as equivalent to confeſſor, or a great ſufferer for the goſpel. Cave ſays (Hiſt. Lit. p. 25.) that Luke lived a ſingle life, and died in the 84th year of his age, about the year of Chriſt 70, but of what death is uncertain. Philoſtorgius informs us, that in the reign of the emperor Conſtantius, the reliques of St. Luke were tranſlated from Achaia to Conſtantinople; and therefore it muſt have been a general perſuaſion in thoſe times, that St. Luke had died, and had been buried in Achaia, which, Gregory Nazianzen ſays, was the province aſſigned to St. Luke. Lardner.

Luke's *Goſpel, St.*, in *Biblical Hiſtory*, the goſpel written by the evangeliſt Luke. That the goſpel and the Acts were written by St. Luke, is a fact that is confirmed by the teſtimony of the moſt unexceptionable of ancient writers. To this purpoſe we may obſerve, that this goſpel is often cited by Juſtin Martyr, who lived A.D. 140, and by the martyrs of Lyons, A.D. 177. Irenæus, A.D. 178, ſays expreſsly, that Luke, the companion of Paul, put down in a book the goſpel preached by him. Clement of Alexandria, A.D. 194, has borne ample teſtimony to this goſpel, as well as the Acts. Tertullian, A.D. 200, aſſerts againſt Marcion the genuineneſs and integrity of the copies of St. Luke's goſpel, owned by himſelf and Chriſtians in general, and for this he appeals to divers apoſtolical churches. Luke's digeſt, ſays this ancient father, is often aſcribed to Paul; it being eaſy to take that for the maſter's which the diſciples publiſhed. Origen, A.D. 230, mentions the goſpels according to the order in which they are now generally received; and "the third," he ſays, "is that according to Luke, the goſpel commended by Paul, publiſhed for the ſake of the Gentile converts." Euſebius of Cæſarea, A.D. 315, ſpeaking of St. Paul's fellow-labourers, ſays, "and Luke, who was of Antioch, and by profeſſion a phyſician, for the moſt part a companion of Paul, who had likewiſe a more than ſlight acquaintance with the reſt of the apoſtles, has left us in two books, divinely inſpired, evidence of the art of healing ſouls, which he had learned from them. One of theſe is the goſpel, which he profeſſeth to have written, as they delivered it to him, "who from the beginning were eye-witneſſes and miniſters of the word," with all whom he ſays likewiſe, he has been perfectly acquainted from the very firſt. The other is the Acts of the Apoſtles, which he compoſed now, "not from what he had received by the report of others, but from what he had ſeen with his own eyes." In the Synopſis, aſcribed to Athanaſius, but ſuppoſed to be written about the end of the fifth century, it is ſaid, "that the goſpel of Luke was dictated by the apoſtle Paul, and written and publiſhed by the bleſſed apoſtle and phyſician Luke." But it is needleſs in this place to cite a greater number of authorities.

As to the time in which this goſpel was written, it may be ſettled without much difficulty. The Acts of the apoſtles were publiſhed A.D. 63 or 64, and not long after the goſpel, as is generally allowed. Accordingly Dr. Mill ſuppoſes, thoſe books to have been two parts of one and the ſame volume, and to have been publiſhed in the year of Chriſt 64. The goſpel itſelf bears internal characters of the time in which it was written. As to the place where it was written, learned writers have differed. Jerom ſays, that Luke, the third evangeliſt, publiſhed his goſpel in the countries of Achaia and Bœotia. Gregory Nazianzen alſo ſays, that Luke wrote for the Greeks, or in Achaia. Grotius ſays, that about the time when Paul left Rome, Luke departed to Achaia, and there wrote his books, which we have. Cave thought that they were written at Rome, and before the termination of Paul's captivity. But it is ſaid by Mill, Grabe, and Wetſtein, that Luke publiſhed his goſpel at Alexandria in Egypt. Dr. Lardner has particularly examined theſe different opinions; and he concludes, that "upon the whole, there appears not any good reaſon to ſay, that St. Luke wrote his goſpel at Alexandria, or that he preached at all in Egypt. It is more probable, that when he left Paul, he went into Greece, and there compoſed, or finiſhed, and publiſhed his goſpel, and the Acts of the apoſtles." Origen was of opinion that this goſpel was written for gentile converts; Jerom ſays, that of all the evangeliſts Luke was beſt ſkilled in the Greek language, and that he wrote his goſpel more eſpecially for gentiles, but Chryſoſtom maintains that he wrote for all in general. Luke himſelf, at the beginning of his goſpel, aſſigns the reaſon of his writing, declaring, that whereas many others had raſhly undertaken to give a relation of the matters which he moſt ſurely believed, he thought himſelf obliged, in order the better to divert us from the uncertain relations of others, to deliver in his goſpel a certain account of thoſe things, which he was well aſſured of from his intimate acquaintance and familiarity with Paul, and his converſation with the other apoſtles. So ſays Euſebius.

St. Luke has inſcribed his two books, his goſpel, and the Acts to Theophilus, by whom ſome underſtand any good Chriſtian in general, others a particular perſon. Auguſtin, Chryſoſtom, and many others, have underſtood Theophilus to be a real perſon. Cave ſuppoſed him to be a nobleman of Antioch; but it ſeems more probable, that if St. Luke publiſhed his books in Greece, as we have already ſtated, Theophilus, to whom they are addreſſed, was a man of the ſame country. It is of greater importance to aſcertain, who are deſignated by the many mentioned by the evangeliſt, who before him had attempted to write hiſtories of Jeſus Chriſt. Epiphanius ſuppoſes, that St. Luke here refers to Cerinthus, Merinthus, and others of that deſcription. Origen and Jerom ſay, that many attempted to write goſpels, as Baſilides, Apelles, and others; and they mention ſeveral ſuch, not received by the church; ſuch as the goſpel of Thomas and Matthias, the goſpel of the Egyptians and of the Twelve. Theophylact ſeems to imagine, that the evangeliſt referred to the two latter goſpels now named. Grabe, while he allows that St. Luke did not refer to the goſpels of Baſilides or Thomas, or ſome others mentioned by Origen, for they were not publiſhed till after St. Luke's death, thinks, that St. Luke might refer to the goſpels according to the Egyptians, and according to the twelve, and ſome others. But againſt this opinion it might be urged, that the goſpel according to the Egyptians was not compoſed before the ſecond century. Dr. Mill is of opinion, that of the many narrations to which St. Luke refers, the two principal were the goſpels according to the

Hebrews, and according to the Egyptians. About the year 58, or ſomewhat ſooner, ſays Mill, were compoſed, by ſome of the faithful, evangelical narrations, or ſhort hiſtories of Chriſt. The writers were not our evangeliſts Matthew and Mark; but ſome of the firſt Chriſtians, who, before Luke, and alſo before Matthew and Mark, wrote hiſtories of the things done by Chriſt, and received from apoſtolical tradition, not with a bad or heretical deſign, but with the ſame deſign with our evangeliſts; but their hiſtories, as we may infer from St. Luke's account, were inaccurate and imperfect, and they contained ſome things not certain, or well atteſted, and poſſibly ſome miſtakes. Dr. Lardner, who upon the whole approves the preceding ſtatement, cannot allow the goſpel according to the twelve, or according to the Hebrews, to have been one of the memoirs or narrations to which St. Luke refers; for theſe were ſhort hiſtories, whereas that was a full goſpel, ſuppoſed to have been either St. Matthew's original Hebrew goſpel with additions, or his original Greek goſpel, tranſlated into Hebrew with additions. Moreover, the goſpel according to the Egyptians could not have been one of theſe memoirs, becauſe it was an heretical goſpel, probably compoſed in the ſecond century by ſome Encratites, who were enemies of marriage. Whatever the memoirs or narrations were, none of them now remain, nor even ſo much as any fragments, nor quotations of them occurring in any Chriſtian writings now extant. Marcion, a heretic who lived in the firſt half of the ſecond century, rejected all the goſpels, except that of St. Luke, and this he mutilated and altered, and interpolated in a great variety of places. He would not allow it to be called the goſpel of St. Luke, eraſing the name of that evangeliſt from the beginning of his copy. Some of his followers conſidered it as written partly by Chriſt himſelf, and partly by the apoſtle Paul. Marcion retrenched the firſt and ſecond chapters entirely, and begun his goſpel at the firſt verſe of the third chapter, and even read this in a manner different from our copies, *viz.* In the 15th year of Tiberius Cæſar, God deſcended into Capernaum, a city of Galilee. Some late Chriſtian writers have concurred in Marcion's retrenchment; but without ſufficient authority. Lardner.

St. Luke, ſays a modern writer, is pure, copious, and flowing in his language, and has a wonderful and entertaining variety of ſelect circumſtances in his narration of our Saviour's divine actions. He acquaints us with numerous paſſages of the evangelical hiſtory, not related by any other evangeliſt: both in this goſpel and Apoſtolical Acts, he is accurate and neat, clear and flowing, with a natural and eaſy grace; his ſtyle is admirably accommodated to the deſign of hiſtory; it had a very conſiderable reſemblance to that of his great maſter St. Paul; and, like him, he had a learned and liberal education, and appears to have been very converſant with the beſt claſſics; for many of his words and expreſſions are exactly parallel to theirs. Blackwall's Sacred Claſſics.

Luke's *Day, St.*, is a feſtival obſerved on the 18th of October.

LULANIS, in *Botany*, a name given by ſome of the ancient Greeks to a plant, uſed very frequently for a yellow colour in dyeing, and by the ladies for tinging their hair yellow, the favourite colour of thoſe times. Neophytus explaining this word, ſays, that it ſignified the ſame with iſatis, glaſtum, or woad; and ſeveral others have been of that opinion, though very abſurdly, ſince the glaſtum or woad dies a blue colour, not a yellow; and by no means anſwers the deſcription of the lulanis, which is the ſame with the lutum, or lutea herba of the Romans, and with the geniſtella tinctoria, or dyers'-weed of theſe times.

LULEA, or Lula, in *Geography*, a ſea-port of Sweden, in Weſt Bothnia, on the N. ſide of the river Lulea, at the N.W. extremity of the gulf of Bothnia, with a good harbour; 68 miles W. of Tornea. N. lat. 65° 38'. E. long. 22° 4'.

LULES, Los, a town of South America, in the province of Tucuman; 50 miles N. of St. Miguel de Tucuman.

LULLI, John Baptist de, in *Biography*, ſecretary to Louis XIV., and ſuperintendant of his muſic, was born at Florence in 1633, having a miller for his ſire. A Cordelier gave him his firſt leſſons in muſic upon the guitar, though he afterwards applied to the violin. He was only thirteen when the Chevalier de Guiſe, being on his travels in Italy, propoſed to his parents to take him into France, and engage Mademoiſelle de Guiſe, his ſiſter, to take him among the officers of her kitchen.

This princeſs having accidentally heard him play on the violin, had him taught, and he became in a ſhort time an excellent performer.

Louis XIV. being deſirous to hear him, was ſo pleaſed with his performance, that in 1652, he appointed him inſpector-general of his violins, and ſoon after created a new band, which was called *les petits violons*. Theſe new muſicians formed by Lulli ſoon became the firſt in Europe, which is not ſaying much for them, as ſuch was the ignorance of the generality of inſtrumental performers at this time, that they could execute nothing which they did not know by heart.

The genius, therefore, of Lulli was obliged to contract itſelf to the abilities of his orcheſtra, and it is ſuppoſed that he would have written as well as his ſucceſſors, if he had lived a hundred years later.

Before the eſtabliſhment of the opera in France, the king every year gave to his court magnificent ſpectacles called *ballets*, in which there was a great number of ſymphonies, mixed with recitatives. Lulli firſt began by only compoſing the muſic to the dances in theſe ballets; but the king became ſo fond of his compoſitions, that he would hear no other.

In 1672, Perrin, to whom the patent for an opera was firſt granted, reſigned it to Lulli, whoſe genius began to expand, and he may be regarded as the creator of this kind of muſic, which (according to M. Laborde) has not been ſo much improved (in France, he ſhould have ſaid) as ſome imagine, and in many particulars has, perhaps, loſt more than it has gained.

It is true, that he was aſſiſted by the immortal Quinault, of whom he had the penetration to diſcover the genius, and the dexterity to ſecure the aſſiſtance by a deed, in which the poet engaged to ſupply him every year with a new drama, for 4000 livres, about 200*l*.

Quinault ſketched many plans, and carried them to the king for his approbation: after which Lulli pointed out to him the places where the dances were to be introduced, and let him hear the airs. The ſcenes were examined, by his majeſty's command, in the Academie des Belles Lettres. Thus by their united opinions, all the dramas of Quinault were regulated, which remain the beſt that were produced in France during the 17th century, and will probably continue the beſt, if new ſet, for many ages yet to come. The enemies of Quinault, jealous of his glory and talents, contrived to bring about a quarrel between the poet and muſician. Lulli had recourſe to La Fontaine, who, at his requeſt, produced the opera of "Daphne," but as ſoon as Lulli had heard it read, he did not conceal from the author, that he thought his talents did not extend to writing operas. La Fontaine, piqued at having laboured in vain, to revenge himſelf on Lulli, for his coarſe rejection of his drama, wrote his comedy, or rather ſatire, of "The Florentine," but as he had a good heart, he ſoon ſubdued his wrath, and they were ſincerely reconciled.

The king, more and more pleaſed with his muſic, conferred on him the title and emoluments of ſecretary to his majeſty, and heaped upon him many other favours for his family.

The king having been extremely ill in 1686, Lulli compoſed a Te Deum on his recovery, which was executed in the church of the Feuillans, Rue Saint Honoré, the eighth of January 1687. In enthuſiaſtically regulating the time with his cane, he ſtruck his foot ſo violently, that, probably from a bad habit of body, a mortification came on. He was at firſt adviſed to have the toe taken off which was wounded by the cane, then the foot, and then the leg. But ſome quacks having promiſed to cure him without amputation, Meſſrs. de Vendôme, who had a ſincere regard for him, offered to the quacks 2000 piſtoles if they cured him, and lodged them in the hands of a banker. But all their efforts were uſeleſs, and it was announced to him that he muſt prepare for death. His confeſſor refuſed to give him abſolution, but upon condition that he would burn the opera of Achilles and Polixene, which he had been preparing for the ſtage. He conſented, and the compoſition was committed to the flames.

Some days after, fancying himſelf a little better as the gangrene encreaſed, one of the young princes of Vendôme came to ſee him; "What! Baptiſt, (ſays he,) haſt thou been ſo fooliſh as to burn ſuch good muſic."—"Huſh, huſh! my lord, (whiſpers Lulli,) I have got a copy of it." However, it is aſſerted, that he manifeſted in his laſt moments a ſincere repentance, and teſtified the higheſt ſenſe of religion. He died at Paris on the 22d of March 1687, in the 54th year of his age. He was buried in the church of Les petits Péres, in La Place des Victoires, where a fine monument was erected to his memory, and where may have been read, before the revolution, the following epitaph by Santeuil:

"Perfida mors, inimica audax, temeraria et excors,
Crudeliſque, et cœca probris te abſolvimus iſtis,
Non de te querimur, tua ſint hæc munia magna.
Sed quando per te populi Regiſque voluptas,
Non ante auditis rapuit qui cantibus orbem
LULLIUS eripitur, querimur modo, ſurdus fuiſti."

Lulli was a fortunate man to arrive in a country where muſic had been ſo little cultivated, that he never had any rival, nor was there throughout the whole kingdom of France an individual who had the courage to doubt of his infallibility in his art. He was fortunate in ſo magnificent a patron, and ſtill more fortunate in a Lyric poet, who could intereſt an audience by all the powers of poetry, by the contexture of his fables, and variety and force of his characters.

Lulli was rough, rude, and coarſe in his manners, but without malice. His greateſt frailties were the love of wine and money. There were found in his coffer 630,000 livres in gold, an exorbitant ſum for the time in which he lived. He had the art of making himſelf at once beloved and feared by the performers of his muſic, which is doubtleſs the moſt eſſential talent for governing ſuch eccentric and mutinous ſubjects; but however difficult it may be to keep them in order and in good humour, true merit, exact juſtice, and a ſteady conduct always ſucceed.

Lulli married the only daughter of Michel Lambert, the celebrated muſician, and the beſt ſinging-maſter of his time. By this marriage he had three ſons and three daughters, to all of whom he left an ample proviſion, and friends in power, who conferred on them places, penſions, and kindneſs.

LULLY, RAYMOND, a philoſopher and chemiſt of great note in the dark ages, was born in the iſland of Majorca in 1236, of an illuſtrious family of that name at Barcelona. From the works that bear his name, it is ſuppoſed that he was ardently attached to the ſtudy of the ſciences, of philoſophy, theology, chemiſtry, and medicine; but there is great doubt as to the genuineneſs of many of thoſe works, which were probably written by his pupils, or even by perſons who lived conſiderably poſterior to his time. In his youth he bore arms, and led the life of a man of pleaſure. It is related of him that he fell in love with a young damſel, named Eleonora, who obſtinately rejected his addreſſes; and, at length, when he was one day ſtrongly preſſing his ſuit, and demanding the reaſon of her refuſal, ſhe expoſed her breaſt conſumed with a cancerous ulcer. This ſpectacle is ſaid to have inſpired him with a reſolution of ſeeking a remedy for her diſeaſe, and to have been the motive which led him to the chemical ſtudies, for which he became celebrated, as well as to a journey into Africa, for the purpoſe of conſulting the works of Geber. But others affirm that the ſight had ſuch an effect upon him, that he plunged into religious retirement, and devoted the reſt of his days to pious purpoſes. It appears certain that he undertook a courſe of travels into Africa and the Eaſt, with the view of converting the Mahometans to the Chriſtian faith, where he incurred greath hardſhips and dangers, and whence he was permitted to depart only upon condition of not returning. He was ſtill, however, ſo much inflamed with zeal for this object, that he entered the Franciſcan order, and again viſited Africa. When he was again found there, he was thrown into priſon, and after ſuffering much torture, was releaſed through the interceſſion of ſome Genoeſe merchants, who took him on board their ſhip; but he died on the paſſage when juſt in ſight of his native land, in 1315. Others aſſert that he was ſtoned to death while preaching to the infidels in Africa, on the 26th of March of that year.

From this narrative, which repreſents Lully in the light of a fanatic miſſionary, we ſhould not expect that ſcientific character which has cauſed his name to be preſerved to modern times. It ſeems, however, that he had travelled in England, France, and Germany; and he calls himſelf a diſciple of Roger Bacon, whom he had probably ſeen in his journey. As a chemiſt, indeed, he appears in an extraordinary light; for although he is believed to have been the firſt who mentioned the philoſopher's ſtone, and though that was the leading object of his reſearches, together with the fancied *panacea*, or univerſal remedy; yet he maintained that chemiſtry was only to be acquired, and theſe objects to be obtained by a ſeries of experiments; and that the art was not to be taught by words. Boerhaave ſays of the chemical works extant in Lully's name, that he has peruſed moſt of them, and finds them beyond all expectation excellent; ſo that he has been tempted to doubt whether they could be the work of that age. "So full," ſays he, "are they of the experiments and obſervations which occur in later writers, that either they muſt be ſuppoſititious, or the ancient chemiſts muſt have been acquainted with many things which paſs for modern diſcoveries."

Lully has alſo been celebrated as a ſcholaſtic metaphyſician. He introduced into the ſchools a "new tranſcendant art," which was diſtinguiſhed by his name, and by means of which a perſon might hold a diſputation for a whole day, upon any ſubject whatever, without underſtanding any thing of the matter. This invention ſuited the genius of the age. It conſiſted in collecting a number of general terms, common to all the ſciences, of which an alphabetical table was to be provided. Subjects and predicates taken from theſe were to be reſpectively inſcribed in angular ſpaces upon circular papers. The eſſences, qualities, affections, and relations of things being thus mechanically brought together, the circular papers of ſubjects were fixed in a frame, and thoſe of predicates were ſo placed upon them as to move freely, and in their revolutions to produce various combinations of ſubjects and predicates, whence would ariſe definitions, axioms, and propoſitions, varying infinitely. This contrivance, worthy of Laputa, was greatly admired in its time, and its author acquired the title of *the moſt enlightened doctor*.

The following are the titles of thoſe of his works which relate to chemiſtry: "De Secretis Naturæ, ſeu de Quinta Eſſentia, Libellus," firſt printed in 1518, 4to. and frequently republiſhed; "Apertorium de veri Lapidis compoſitione," 1546; "Teſtamentum duobus Libris univerſam Artem Chemicam complectens. Item ejuſdem Compendium animæ tranſmutationis Artis metallorum," 1566; "Liber Mercuriorum;" "De Arte brevi;" "Secreta Secretorum;" "Codicillus, ſeu Vade Mecum, in quo fontes Alchymicæ Artis et Philoſophicæ reconditioris uberrimè traduntur." Many manuſcript eſſays of Lully are preſerved in the library at Leyden, and upwards of a hundred, it is ſaid, which have never been publiſhed, in that of Venice. A complete edition of all the writings attributed to this author was publiſhed at Mayence in 1714, including treatiſes on theology, morals, medicine, chemiſtry, phyſics, law, &c. Gen. Biog. Eloy Dict. Hiſt.

LULLY'S *Art*. See ART, and the preceding article.

LULOLA, in *Geography*, a ſtrong town in Angola, ſituated on an iſland about 100 miles from the mouth of the Coanza, fortified by the Portugueſe.

LULWORTH, EAST, a pariſh in the hundred of Winfrith, in Blandford diviſion of Dorſetſhire, England, is ſituated ſix miles from Wareham, and 116 from London, and contains 74 houſes and 364 inhabitants. The chief object worthy of notice here is Lulworth caſtle, the ſeat of —— Weld, eſq. It is ſituated in the ſouth-eaſt corner of an extenſive park, which occupies a circuit of nearly four miles and a half, and has been lately ſurrounded by an excellent ſtone wall, upwards of eight feet high. The preſent edifice, which was built on or near the ſcite of a caſtle mentioned ſo far back as the year 1146, was commenced in 1588, and finiſhed in 1609, except the internal decorations, which were not completed till after the year 1641, when the anceſtor of the late owner purchaſed the eſtate. The caſtle is an exact cube of eighty feet, with a round tower at each corner thirty feet in diameter, and riſing ſixteen feet above the walls, which, as well as the towers, are embattled. The hall and dining-room are ſpacious, and the rooms in general eighteen feet high. The principal front is on the eaſt, and is faced with Chilmark ſtone, decorated with ſtatuary. In the year 1789, during their majeſties' reſidence at Weymouth, Mr. Weld had ſeveral royal viſits, the particulars of which are recorded in two inſcriptions over the entrance to the caſtle. Mr. Weld has lately erected an elegant little chapel for the convenience of his family; this ſtructure is of a circular form, increaſed by four ſections of a circle, ſo as to form a croſs, and finiſhed with a dome and lantern. The pariſh church of St. Andrew (which was an ancient and curious fabric) has been recently rebuilt at the expence of Mr. Weld.

United with the foregoing pariſh, and about a mile diſtant towards the ſea, is that of Weſt Lulworth, which contains 73 houſes and 312 inhabitants. At a ſmall diſtance is Lulworth Cove, a ſort of natural baſin, into which the ſea flows through a wide gap in the cliff, ſufficient for the entrance of veſſels of 70 or 80 tons burthen. About a mile from the cove is the Arched Rock, which projects from the land into the ſea, having an opening near 20 feet high in the middle, formed like an arch, through which the proſpect of the ſea has a peculiar effect. Beauties of England and Wales, vol. iv.

LUMACHELLE MARBLE. See MARBLE.

LUMAMPA, in *Geography*, a town of South America, in the province of Tucuman; 90 miles S. of St. Yago del Eſtero.

LUMBAGO, in *Medicine*, ſignifies a pain in the loins (*lumbi*), eſpecially from rheumatiſm, affecting the ligaments of the ſpine, or the muſcles of the back. See RHEUMATISM.

The only diſeaſes which are liable to be miſtaken for *lumbago* in general, are painful affections of the kidnies, which, it is well known, are ſeated within the lumbar region on each ſide of the ſpine; eſpecially inflammation of theſe glands, or the formation of calculi in them, or the paſſage of theſe concretions through the ureters towards the bladder. The ſymptoms, attendant upon theſe diſorders of the kidnies, will be found deſcribed in their proper places. (See NEPHRALGIA, NEPHRITIS, and GRAVEL.) We may obſerve here, that, in *lumbago*, the pain does not follow the courſe of the ureters, it is not accompanied with retraction of the teſticle in men, it is not increaſed by external preſſure, it is often little felt, except in the erect poſture, and there is no vomiting, nor any change in the quantity or quality of the urine; the contrary of all which is obſerved in inflammatory and calculous affections of the kidnies.

The internal remedies, commonly adminiſtered for the cure of other forms of rheumatiſm, are alſo beneficial in the lumbago; ſuch as opiates, with antimonials and other ſudorifics, taken at bed-time, and followed by laxatives in the morning, or combined with laxatives, eſpecially the ſubmuriate of mercury, preparations of ſulphur, or ſalts. Much relief, however, is afforded by the application of local ſtimulants to the lumbar region externally. Liniments of camphor, turpentine, and ſimilar ſubſtances, have been found from the experiments of Dr. Home, Dr. Ferriar, and others, among the moſt efficacious of theſe applications. Dr. Ferriar affirms, that he has found a ſolution of camphor in ſulphuric ether relieve the pains of diſeaſed joints, after all other applications had failed ; and he relates ſeveral caſes in which a liniment, reſembling that propoſed by Dr. Home, proved an effectual cure for lumbago. He uſed two drams of camphor, an ounce of baſilicon, and half an ounce of black ſoap, omitting the oil of turpentine, ammonia, and ſeeds of cyminum, preſcribed by Dr. Home. The effect of this application, he ſays, is commonly the removal of the pain within three days, often in a much ſhorter time. See Ferriar. Med. Hiſt. and Reflect. vol. i. p. 188. Home, Clin. Exper. p. 261, § xiv.

LUMBALIS, in *Anatomy*, an epithet applied to ſome parts placed about the loins. The lumbar arteries are branches of the aorta, and the lumbar veins terminate in the inferior vena cava. (See ARTERY and VEIN.) The lumbar nerves are five pairs proceeding from the medulla ſpinalis. (See NERVE.) The lumbar muſcles are the *pſoæ* ; which ſee. For an account of the lumbar vertebræ, ſee SPINE. The lumbar region of the abdomen is the lateral and poſterior part of the umbilical region, the part, in ſhort, which conſtitutes the loins in common language. See ABDOMEN.

LUMBAR, in *Geography*, a town of Spain, in Navarre ; 15 miles N. of Sangueſa.

LUMBAR *Abſceſs*, in *Surgery*. See PSOAS *Abſceſs*.

LUMBERTON, in *Geography*, a poſt-town of America, in North Carolina, and capital of Robeſon county, on Drowning creek ; 32 miles S. of Fayetteville ; it has a court-houſe, and about 36 dwelling-houſes.

LUMBI, in *Anatomy*. See LOINS.

LUMBO, in *Geography*, a town of Benguela ; 120 miles E.N.E. of Benguela. S. lat. 11° 45′.

LUMBORUM QUADRATUS, in *Anatomy*, iléo-coſtien of Dumas, a muſcle ſituated towards the ſide and lower part of the vertebral column, and extending from the criſta of the os innominatum, and the ileo-lumbar ligament, to the lower edge of the laſt falſe rib, and to the tranſverſe proceſſes of the four firſt vertebræ of the loins. It has the form of an elongated ſquare, but is rather broader below than above. Its anterior ſurface is covered above by the diaphragm, then by the anterior lamina of the aponeuroſis of the tranſverſus abdominis, and towards the inſide by the pſoas. It correſponds to the kidney and to the colon. Its poſterior ſurface is covered by the middle aponeuroſis of the tranſverſus, which ſeparates it from the common maſs of the ſacro-lumbalis and longiſſimus dorſi. The outer edge is inclined a little from above downwards, and from within outwards, and correſponds to the angle formed by the ſeparation of the anterior poſterior laminæ of the aponeuroſis of the tranſverſus abdominis. The inner margin is attached to the points of the tranſverſe proceſſes of the four firſt lumbar vertebræ by as many flattened pieces. The lower edge is attached to the middle of the poſterior part of the criſta ilii, for an extent of about two inches ; it is alſo fixed to the ileo-lumbar ligament. The upper edge is inſerted in the lower margin of the laſt falſe rib, for a more or leſs conſiderable extent in different ſubjects ; in ſome it occupies nearly the whole length, in others only the inner third part.

It is fixed to the criſta of the os innominatum by aponeuroſes, which aſcend to a conſiderable height on the anterior ſurface and the outer edge. Theſe fibres, which proceed from below upwards, are croſſed below by others, which ariſe from the tranſverſe proceſs of the laſt lumbar vertebræ. The fleſhy fibres aſcend rather obliquely from without inwards, and the internal are the ſhorteſt ; they terminate at the tranſverſe proceſſes of the lumbar vertebræ by tendinous fibres. The external and longer ones end at the lower edge of the laſt falſe rib by ſhort aponeuroſes. Sometimes another muſcular ſtratum ariſes from the front of the tranſverſe proceſſes of the third and fourth lumbar vertebræ, paſſes obliquely outwards, and is blended with the reſt of the muſcle.

The quadratus lumborum inclines the loins towards its own ſide ; when theſe are fixed, it may raiſe the pelvis on that ſide, and lower it on the oppoſite. By drawing downwards the laſt falſe rib, it may be concerned in reſpiration.

LUMBRE, in *Geography*, a town of France, in the department of the Straits of Calais, and chief place of a canton, in the diſtrict of St. Omer. The place contains 502, and the canton 13,655 inhabitants, on a territory of 262½ kiliometres, in 36 communes.

LUMBRERAS, a town of Spain, in Leon ; 22 miles N.N.W. of Civdad Rodrigo.

LUMBRICALES, in *Anatomy*, certain ſmall muſcles of the fingers and toes, connected with the flexor tendons of thoſe organs. See FLEXOR.

LUMBRICOIDES. See ASCARIS.

LUMBRICUS, EARTH-WORM, in *Natural Hiſtory*, a genus of the vermes-inteſtina claſs and order. Body round, annulate, with generally an elevated fleſhy belt near the head, moſtly rough, with minute concealed prickles placed longitudinally, and furniſhed with a lateral aperture. There are ſixteen ſpecies contained in this genus, of which four are natives of this country.

Species.

* TERRESTRIS ; Common earth-worm, ſometimes named dew-worm. Body red, with eight rows of prickles. There is another variety exactly like this, only half the ſize. The body contains about one hundred and forty rings, each of which has four pair of prickles, not viſible to the naked eye, but diſcoverable to the touch : when expanded, it is convex on each ſide ; but when contracted, it is flattiſh beneath, with a red canal down the body ; the belt is wrinkled and porous ; mouth placed beneath the proboſcis. It inhabits decayed wood and common ſoil, which, by perforating, it renders fit to receive the rain : it devours the cotyledons of plants, and wanders about by night ; it is the food of moles, hedge-hogs, and various birds.

This worm has neither bones, brains, eyes, nor feet. It has a number of breathing holes ſituated along the back, and near each ring. The heart is placed near the head, and may be obſerved to beat with a very diſtinct motion. The ſmall rings are furniſhed with a ſet of muſcles, that enable it to act in a ſort of ſpiral direction ; and by this means it is capable, in the moſt complete manner, of creeping on the earth, or penetrating into its ſubſtance. Theſe muſcles enable the worm to contract or dilate its body with great force. The rings are each armed with ſmall ſtiff ſharp prickles, which the animal is able to open out or cloſe upon its body ; and from beneath the ſkin there is ſecreted a ſlimy matter, which, by lubricating the body, greatly facilitates its paſſage through the earth.

This worm has been confounded with the ASCARIS *Lumbricoides*, or round worm of the human inteſtines ; which ſee. The difference between the two may be briefly pointed out in this place.

The common earth-worm has its extremities much blunter than thoſe of the inteſtinal ; its mouth conſiſts of a ſmall, longitudinal fiſſure, ſituated on the under ſurface of a ſmall rounded head, there being no appearance of the three veſicles which are found in the aſcaris. On the under-ſurface of the earth-worm there is a large ſemi-lunar fold of ſkin, into which the head retreats ; but this is wanting in the aſcaris. The anus of the earth-worm opens at the very extremity of the tail, and not, as in the aſcaris, at a conſiderable diſtance from it. The aſcaris wants the tranſverſe rugæ, which are ſo ſtrongly marked in the earth-worm, as well as the broad yellowiſh band by which the body of the latter is ſurrounded.

The internal ſtructure of the two worms is alſo extremely different. In the earth-worm there is a complete and large ſtomach, conſiſting of two cavities; and the inteſtinal canal in the latter is larger, and more formed into ſacculi than in the aſcaris. The parts ſubſervient to generation in theſe worms are very different: in the aſcaris there is a diſtinction of ſex, but the common earth-worm is hermaphrodite.

Dew-worms, though a ſmall, and frequently regarded as a deſpicable link in the chain of nature, would, if loſt, be greatly miſſed by thoſe who are apt to conſider them as a nuiſance. For, independently of their affording a large ſupply of food to birds, &c. already noticed, they are of great uſe in promoting vegetation, by boring, perforating, and looſening the ſoil, and rendering it pervious to rain and the fibres of plants, by drawing ſtraws and ſtalks of leaves and twigs into it; and, moſt of all, by throwing up ſuch numbers of lumps called worm-caſts, which act as a fine manure for grain and graſs.

* Marinus; Lug. Back with two rows of briſtly tubercles; body pale red, round, and annulate, with greater or leſs rings; the firſt prominent, with two oppoſite tufts of ſhort briſtles on each, the lower part ſmooth. It is found on the ſhores of England, and other parts of the European coaſt, where it buries itſelf in the ſand to a great depth, leaving a little riſing with an aperture on the ſurface. It is uſed as a bait for fiſhes.

Vermicularis. Body white, with two rows of prickles. It inhabits the wet and decayed trunks of trees, and among moiſt leaves, moving very expeditiouſly in moiſt places, but twiſting itſelf up in dry ones. Its body is poliſhed and glabrous.

Variegatus. Rufous ſpotted, with ſix rows of prickles. It inhabits wet plantations, and is the moſt beautiful of the whole genus. The body red, very finely teſſellate with brown, having a ſanguineous line running down the whole body. It eaſily breaks in pieces, and as eaſily reproduces what has been loſt by accident or otherwiſe.

Tubifex. Body reddiſh, with two rows of prickles; the body is pellucid, very ſimple, thin, and truncate at the tip, with a dark inteſtine. It is found at the bottom of rivulets, where it forms a perpendicular tube of earth for its habitation.

Lineatus. Body white, with a longitudinal red line. Found very abundantly on the ſhores of the Baltic, among ſea-weed. It is pellucid, with rather a ſhort body, having a yellow artery on the back, and a bifid vein towards the head.

Ciliatus. Body rufous, and ciliate between the rings; the body is glabrous, with about forty ſegments; the interſections are armed with four tufts of ſhort briſtles.

Tubicola. White, with a red dorſal ſpot on each of the ſegments. This ſpecies is found in the bays of Norway that have a clayey bottom, in a round membranaceous tube, covered with mud, and about an inch longer than itſelf. It has twenty-five ſegments in the body, of which the interſections are armed with two briſtles on each ſide; the inteſtine is black, and running down the whole body.

Echiurus. Body covered with rows of granulations; the hind-part obtuſely truncate, and ſurrounded with a double crown of briſtles. It inhabits the ſandy bottom of the ſhores of Belgium; is moſt obſervable in winter, and is the chief food of cod-fiſh. Body whitiſh-grey, with fulvous viſcera, about the ſize of a perſon's middle finger; tongue fleſhy, thickiſh, and boat-ſhaped.

* Thalassema. Body ſtriate, dirty red, with ſhining red ſpots, beneath grey; mouth ſurrounded with a funnel-like tube, which is wrinkled within, and plaited at the margin; the body is glabrous, mucous, thicker at one end, and ſomewhat pointed at the other; the mouth is placed above, with a ſaffron funnel. Inhabits the ſhores of Cornwall.

Edulis. Body whitiſh-fleſh-colour, ſubclavate behind, dilated and papillous before; mouth terminal, and ſurrounded with a villous rim or wrinkle. There are two hundred and ſeventy-eight rings between the villous part and the hinder end, ſeparated by an annular ſtria; the hind-part bulbous, with a double papilla; the fore-part beſet with numerous fleſh-coloured ones diſpoſed in tranſverſe rows.

* Oxyurus. Body whitiſh-livid, very ſharp at the hind extremity, and obtuſe before, with a round, retractile, and exſertile proboſcis. This ſpecies is found on the Suſſex coaſt, is about an inch and a half long, and annulate with very fine ſtriæ; ſnout truncate, and very fine, granulate, with a pore at the baſe ſcarcely viſible.

Fragilis. Body red, with lateral divided warts, and faſciculate briſtles. The body of this ſpecies reſembles the terreſtris, with above five hundred ſmooth and very brittle rings; the head is conic, with an approximate wrinkled mouth. It inhabits the muddy bottom of the bays of Norway.

Armiger. Body red, with double lanceolate lamellæ on the belly, and none on the fore-part; is about two inches long, and conſiſting of about two hundred rings. Found in the iſlands of Norway.

Cirratus. Body armed with very long cirri. Inhabits the Norway ſeas.

Sabellaris. Body jointed, and truncate at one end; the interſections of the joints thick, and armed with two prickles. It reſembles the tubicula, and is found in the Norwegian ſeas.

LUMELLA, in the *Glaſs-trade*, the round hole in the floor of the tower of the leer, which is directly over the working ſurface, and by which the flame is let into the tower.

LUMELLO, in *Geography*, a town of Italy, in the department of the Gogna. This place lately gave name to a diſtrict in the duchy of Milan, called "Lumalline," on the Gogna; once the reſidence of the kings of Lombardy, now a village; 26 miles S.W. of Milan. N. lat. 48° 57′. E. long. 8° 47′.

LUMHAGAN, an iſland in the ſtraits of Malacca, near the coaſt of Salengora, 12 miles long, and 5 broad; ſeparated from the continent by a narrow channel, called the "ſtraits of Lumhagan." N. lat. 2° 54′. E. long. 101° 24′.

LUMIJOCKI, a town of Sweden, in Eaſt Bothnia; 12 miles S.W. of Ulea.

LUMINOSA Semita. See Semita.

LUMINOUS Column, and *Fire*. See the ſubſtantives.

Luminous *Emanations*, have been obſerved from human bodies, as alſo from thoſe of brutes. The light ariſing from currying a horſe, or from rubbing a cat's back, are known to moſt. Inſtances of a like kind have been known on combing a woman's head. Bartholin gives us an account, which he entitles "mulier ſplendens," of a lady in Italy, whoſe body would ſhine, whenever ſlightly touched with a piece of linen. Theſe effluvia of animal bodies have many properties in common with thoſe produced in glaſs; ſuch as their being lucid, their ſnapping, and their not being excited without ſome degree of friction; and are undoubtedly electrical, as a cat's back has been found ſtrongly electrical when ſtroaked. See ELECTRICITY and LIGHT.

Human bodies not only appear luminous, but even the exhalations from them adhering to their clothing will cauſe it to ſhine likewiſe.

LUMINOUSNESS *of the Sea*. See LIGHT and SEA.

LUMIO, in *Geography*, a town in the iſland of Corſica; 5 miles N.E. of Calva.

LUMME, in *Ornithology*. See COLYMBUS *Troile*.

LUMO, in *Geography*, a town of the iſland of Cuba; 45 miles S.S.W. of Havannah.

LUMP-FISH, in *Ichthyology*. See CYCLOPTERUS *Lumpus*.

LUMP *of Fleſh*, in the *Manege*. See BOUILLON.

LUMPARAN, in *Geography*, an iſland of Sweden, eaſt of Aland, between the Baltic and the gulf of Bothnia. N. lat. 60° 7′. E. long. 20° 3′.

LUMPEN, in *Ichthyology*, the name of a fiſh, common in the markets at Antwerp, of a long and round body, growing gradually ſlenderer to the tail. Its colour is a greeniſh-yellow, with black broad lines on the back, placed tranſverſely; and it has a little redneſs at the end of its tail.

The lumpen is a ſpecies of the blenni, diſtinguiſhed by Artedi by the name of the *blennius*, with fins like cirri under its neck, and tranſverſe ſtreaks on the back. The cirri are bifid.

LUMPOKOLSKOI, NIZNEI, in *Geography*, a town of Ruſſia, in the government of Tobolſk, on the Oby. N. lat. 61°. E. long. 76° 54′.

LUMPOKOLSKOI, *Verchnei*, a town of Ruſſia, in the government of Tobolſk. N. lat. 60° 54′. E. long. 78° 22′.

LUMPS, in *Rural Economy*, a term made uſe of to ſignify barn-floor bricks, in ſome places.

LUNA, in *Aſtronomy*. See MOON.

LUNA, in *Ancient Geography*, *Lunegiano*, a town ſituated on the Macra, which had a port in Liguria, called "Lunæ Portus," which, according to Strabo, was a very large and fine harbour, containing ſeveral others. The town was ſituated to the weſt of the mouth of the river Macra, and was afterwards called "Cariaram," both names alike ſignifying Luna, the moon, and referring to its form, which was that of a creſcent. Lucan ſpeaks of its aruſpices; Servius and Martial of its cheeſe, marble, and wine. According to Strabo, it was deſtroyed by Nero; and ſome of its ruins are ſtill viſible in a place called Lunigona, and its ſmall territory is named Lunegiano. M. Gebelin conjectures that the name Luna was derived from the Celtic *lun*, water.

LUNA, in *Geography*, a town of Spain, in Arragon; 22 miles W. of Hueſca.—Alſo, a town of Lithuania, in the palatinate of Troki; 16 miles S.E. of Grodno.

LUNA *Cornea*, in *Chemiſtry*, is the combination of marine acid with ſilver, or the white curdy precipitate of muriat of ſilver, which takes place, when the nitrat, acetat, or any other ſoluble ſalt of ſilver comes in contact with muriatic acid, either ſingle or in any ſoluble combination. See SILVER.

To make this combination, the ſilver is firſt diſſolved in nitrous acid; to this ſolution marine acid, or more uſually common ſalt diſſolved in water, is added. The mixture ſoon becomes turbid, and a copious precipitate is formed in it, which has always the appearance of curd. The ſolution of ſalt is added, till no more precipitate is formed. The precipitate, when ſeparated from the liquor that ſwims over it, is called luna cornea; becauſe if this matter be expoſed alone to fire, the acid carries off with it a portion of the ſilver, and the remaining matter melts, aſſuming the form of a horny ſubſtance.

The beſt method of reducing luna cornea, or of ſeparating ſilver from marine acid, according to Margraaf, is to diſſolve half an ounce of fine ſilver in aquafortis, to precipitate it by a ſea-ſalt, and edulcorate the precipitate, which will then weigh five drams ſixteen grains. For the reduction of this precipitate, mix it with an ounce and a half of dry volatile ſal ammoniac, triturate them well together with a little water during a quarter of an hour; then add three ounces of mercury obtained from cinnabar by means of quick-lime, and continue to triturate during ſome hours with a little more water. Thus an amalgam will be formed, which being waſhed from a white powder and dried, will weigh three ounces and half a dram. By diſtillation of this amalgam, a reſiduum of ſilver, four grains leſs than the original half ounce, will be obtained. By ſubliming the white powder, which weighs five drams, three grains of ſilver will be obtained; but if the amalgam and white powder be diſtilled together, the operation will fail, and the luna cornea be recompoſed. (Berlin Mem. 1749.) M. Beaume ſays, that luna cornea may be reduced without loſs by fuſion with four times its weight of fixed alkali.

Luna cornea mixed with ſea-ſalt and tartar rubbed on braſs gives a ſilver-like appearance; and is the ſubſtance employed for the ſilvering of the dial-plates for clocks. A more ſubſtantial ſilvering may be given by the above mixture, if the piece of braſs to be ſilvered be previouſly heated conſiderably, and cleaned with a ſcratch bruſh; and if the operation be repeated, till the ſilver ſeems to be ſufficiently thick. The braſs having a ſtronger diſpoſition to unite with the marine acid than the ſilver has, ſeparates this acid from the ſilver, which is then precipitated upon the ſurface of the braſs plate. The luna cornea will alſo ſerve in examination of mineral waters, or of any other liquor, to diſſolve if they contain marine acid in whatever baſe it be engaged, except metallic baſes; for if theſe waters contain the ſmalleſt quantity of marine acid, a luna cornea will be precipitated by them from a ſolution of ſilver in nitrous acid, and this luna cornea is known by its acid-like appearance. Macquer, Chem. Dict. Engl. edit.

LUNAR *Month.* See MONTH.

LUNAR *Obſervations*, or *Lunar Method*, is the method of finding the longitude, by taking the diſtance between the moon and the ſun, or a fixed ſtar, which has been already explained under the article LONGITUDE; but the great importance of this problem induces us here to give a further and more minute explanation of its principles and operations, and of the different methods that have been deviſed for obtaining the ſolution.

This method of finding the longitude is the greateſt modern improvement in navigation: the idea, however, is not modern, but it has not been applied with any ſucceſs until within the laſt fifty years. M. de la Lande mentions certain aſtronomers who, above two hundred years ago, propoſed this method, and contended for the honour of the diſcovery; but its preſent ſtate of improved and univerſal practice he very juſtly aſcribes to Dr. Maſkelyne. The diſcovery, indeed, ſeems to claim leſs honour than its ſubſequent improvements; it is one of thoſe things which are obvious in theory, but difficult in practice. The moſt ancient method of finding the longitude was by the lunar eclipſes; and that of finding it by the lunar diſtances is perfectly analogous: it is therefore highly probable that the method was thought of at a very early period, but the want of proper tables and apparatus prevented its being reduced to practice.

It may be obſerved, that, in the moſt practical methods of finding the longitude at ſea by celeſtial obſervations, the moon is the chief guide or inſtrument; for the quickneſs of her motion renders her peculiarly well adapted for meaſuring ſmall portions of correſpondent time. Now, as ſhe is ſeen in the ſame part of the heavens nearly at the ſame inſtant of abſolute time, from all parts of the earth where ſhe is viſible, and as ſhe is continually and ſenſibly changing her place, it is evident that if two correſpondent obſervers were to note the preciſe moment of their reſpective times, when ſhe is ſeen in any particular part of the heavens, *the difference between thoſe times would ſhew the difference of longitude.*

In every method of finding the longitude by the moon, the firſt object is to be able to aſcertain the part of the heavens where ſhe is: this is eaſily ſeen at the time of her eclipſes, or at the occultation of a fixed ſtar; and theſe were naturally the firſt methods reſorted to, but they occur too ſeldom for general uſe: the moon's place, however, may be marked with equal preciſion, by taking her diſtance from ſome fixed object, whoſe latitude and longitude are known; and ſtars in or near the zodiac are preferred, as the nearer ſuch objects are to the moon's orbit, the greater will be her motion with reſpect to them: and though her motion is not uniform, yet, during the ſhort ſpace of time that ſhe is near any ſtar, ſhe may be conſidered as moving uniformly.

It has been above obſerved, that if two perſons under different meridians were to mark the moon's place, and alſo their relative times of obſervation, they might thence tell their difference of longitude; but they could not communicate their obſervations ſufficiently ſoon for practical purpoſes; and even admitting the poſſibility of this, it were neceſſary that the longitude of one place ſhould be known, in order to determine that of the other. Now the Nautical Almanac is calculated to ſupply all theſe wants. This admirable work may be conſidered a perpetual obſerver, that communicates univerſally and inſtantaneouſly certain celeſtial appearances, as they take place at Greenwich Obſervatory. Here the diſtances are given between the moon and the ſun, and certain remarkable ſtars in or near the zodiac, for every three hours; and any intermediate diſtance, or time, may be thence found by the rule of proportion with ſufficient accuracy. If, therefore, under any meridian, a lunar diſtance be obſerved, *the difference between the time of obſervation and the time in the Almanac, when the ſame diſtance was to take place at Greenwich, will ſhew the longitude.* For example, if the obſerved diſtance between the ſun and moon be 50° at eight o'clock, but by the Almanac the ſame diſtance of 50° will take place at Greenwich at ſix, it is evident that the difference between the obſerved and computed time is two hours, and therefore the longitude is 30°; and it is alſo clear that the longitude is eaſt, the time being moſt advanced at the place of obſervation.

A method ſo apparently ſimple muſt have been long ſince adopted; but two difficulties occured: one the want of proper inſtruments, which want has been happily ſupplied by the invention and ſubſequent improvement of Hadley's quadrant; and the other, correct lunar tables; for the moon, though ſo near and ſo conſpicuous to the earth, has always perplexed aſtronomers more than any other celeſtial body. The various inequalities of her motions were never properly underſtood, until ſir Iſaac Newton diſcovered the phyſical laws which govern them; and from his theory profeſſor Mayer formed lunar tables, which have been found ſufficiently correct for nautical practice, and from which thoſe tables in the Nautical Almanac of the lunar diſtances had been calculated under the direction of Dr. Maſkelyne for many years. In 1806 the French board of longitude publiſhed new lunar tables, calculated by Du Burgh, from the theory of La Place and the obſervations of Dr. Maſkelyne; and from theſe tables the lunar diſtances in the Nautical Almanac of 1813 are computed, and in the Almanacs that follow.

The above two difficulties having been obviated, a third ſeems ſtill to remain; and though this is in ſome meaſure removed by the application of the Nautical Almanac and Requiſite Tables, yet the calculation is ſtill more tedious than might be wiſhed; nor is it poſſible to render it much ſhorter, as the problem neceſſarily comprehends ſolutions in two ſpheric triangles: this ariſes from the circumſtance of the *obſerved diſtances* between the heavenly bodies not being the *true diſtances*; for the altitudes of thoſe bodies are more or leſs affected both by refraction and parallax; and though theſe effects only operate in a vertical direction, yet that which changes the altitude of two bodies muſt alſo change their diſtance aſunder. This is evident from the conſideration, that the altitude of a celeſtial object is an arc of an azimuth circle intercepted between the object and the horizon; and as all azimuth circles incline gradually to each other from the horizon to the zenith, where they meet, it is plain that the more two bodies are apparently raiſed, the leſs will be their apparent diſtance aſunder, and the contrary.

It is well known that the heavenly bodies are raiſed by refraction, and depreſſed by parallax; and that theſe effects are greateſt in the horizon, and gradually diminiſh to the zenith, where they become nothing. Refraction depends upon altitude alone, but parallax depends upon both altitude and diſtance. All celeſtial objects, except the moon, are more affected by refraction than by parallax, and therefore appear above their true places; but the moon is always ſeen, excepting in the zenith, below her true place, being more affected by parallax than refraction, on account of her proximity to the earth.

Theſe effects of parallax and refraction, though counteracting each other, ſeldom do it ſo equally as to render all correction unneceſſary. Sometimes the *apparent* diſtance is nearly a whole degree more or leſs than the *true* diſtance; and the principal cauſe of ſo great a difference is the moon's parallax: for this body, which is the chief guide to the longitude, is alſo the great cauſe of error in the diſtances, and is therefore the principal object of correction.

In making a lunar obſervation, four perſons are generally employed, one of whom takes the diſtance, two the altitudes, and the fourth notes the time. Theſe things ſhould be performed at the ſame inſtant; and if the obſervation be repeated ſeveral times, and a mean taken, the work is likely to be the more correct: and great care is here neceſſary, for an error in this part of the operation, particularly in taking the diſtance, will pervade the ſubſequent parts of the work, and will of courſe produce a wrong ſolution. The manner of adjuſting the inſtruments, and of making the obſervations, is beſt taught by practice. Thoſe who wiſh for written inſtructions on the ſubject are referred to the Britiſh Mariner's Guide by Dr. Maſkelyne, to Dr. Mackay's book upon the longitude, or to profeſſor Vince's Practical Aſtronomy.

Of correcting the Altitudes of the obſerved Objects.—When a lunar obſervation is made, the firſt object is to clear the altitudes from ſemidiameter, dip, refraction, and parallax.

The moon's parallax in altitude muſt be next calculated; by ſaying, *As radius is to the ſine of her zenith diſtance, ſo is the ſine of her horizontal parallax* (as given in the Nautical Almanac) *to the ſine of her parallax in altitude.*

In correcting the moon's altitude, an allowance ſhould be made for the augmentation of her ſemidiameter, which gradually takes place from the horizon to the zenith. This increaſe is given, in the IVth of the Requiſite Tables, for every five degrees of altitude, which correction is to be added to her horizontal ſemidiameter given in the Nautical Almanac.

The augmentation of the moon's ſemidiameter is cauſed by her being nearer to the ſpectator in the zenith than in the horizon by a ſemidiameter of the earth—for the magnitude of a body is in the inverſe ratio of its diſtance from the obſerver; and as the earth's ſemidiameter bears a very ſenſible proportion to the moon's diſtance, ſhe is ſeen under the greateſt angle in the zenith, which angle gradually diminiſhes to the horizon.

There are other corrections of the altitudes which may be neceſſary in caſes of particular nicety, but which are ſeldom noticed at ſea. Theſe are—an allowance for the contraction of the vertical ſemidiameters of the ſun and moon by refraction; a correction of the moon's parallax, ſuppoſing the earth an oblate ſpheroid; a correction for the refraction, according to the actual ſtate of the atmoſphere, as ſhewn by a thermometer and barometer, and not according to the mean aſtronomical refraction which is commonly uſed. Theſe corrections, though perhaps neceſſary towards the perfection of this problem, being very ſmall, and frequently counteracting each other, are generally conſidered of little conſequence in nautical practice, where greater errors are unavoidable.

From the corrected Altitudes to find the true Diſtance.—It is eaſy to conceive, that by a lunar obſervation, the three ſides of a ſpheric triangle are meaſured in the heavens, which ſides are the apparent co-altitudes of the obſerved bodies, and their apparent diſtance aſunder.

The co-altitudes or zenith diſtances being corrected, the queſtion is, to find the true diſtance between the obſerved bodies; but here there are only two things given, and therefore it cannot be performed until the angle at the zenith is known, which is determined from the three given ſides of the triangle, by the rules of ſpheric trigonometry.

As the effects of parallax, refraction, &c. operate only in a vertical direction, it is evident that the corrections of the zenith diſtances or containing ſides will not change the included angle at the zenith; and therefore three things are now known, namely, the corrected zenith diſtances and the included angle, whence the other ſide is determined by ſpherics, and this ſide is the true diſtance ſought.

A General View of the different Methods of working the Lunar Obſervations.—Few problems have been ever more inveſtigated or ſtudied than that of clearing the lunar diſtance, and many ingenious methods have been deviſed for contracting the operation. Theſe methods are founded on ſome of the following general principles.

The firſt general principle is ſpheric trigonometry, as before explained; the ſecond is the doctrine of proportional errors, by which the effects that the errors in the altitudes produce on the diſtance are ſolved by fluxions, or by the *differential calculus:* and a third principle has been lately diſcovered, which is founded on the properties of a quadrangle inſcribed in a circle, as explained and exemplified by the inventor, Dr. Andrew, in his Aſtronomical and Nautical Tables.

Various methods of working the lunar obſervations have been deviſed chiefly by Halley, Euler, Mayer, Maſkelyne, Lyons, Witchell, Burrow, Borda, Wales, Mackay, Kelly, Gerrard, Andrew, and Mendoza. The methods of the two laſt authors appear the moſt conciſe, but all are ſufficiently correct, and ſeamen generally prefer ſuch as they have firſt learnt. It may indeed be obſerved, that operations which appear the moſt conciſe are not always the moſt expeditiouſly performed, as much depends on the number and variety of tables required, and the manner of applying them. No method has hitherto obtained an excluſive preference over the reſt, nor does it appear poſſible to reduce the calculation to a conciſeneſs to anſwer the general purpoſes or wiſhes of ſeamen; and hence, other modes have been deviſed, of obtaining approximate ſolutions by projection or graphic operation.

The firſt graphic method for clearing the diſtances was that by La Caille, called the *Chaſſis de reduction,* which has ſince been copied by La Lande, Mackay, and others. It is an orthographic projection, conſiſting of a great number of lines accurately drawn, and various ſcales for obtaining the different corrections.

Another graphic operation, of a different deſcription, was executed by the late George Margetts, and publiſhed in 1790. It conſiſts of ſeventy large plates, containing numerous lines drawn from the ſolutions of lunar diſtances in Dr. Shepherd's Tables. By Margetts' Longitude Tables the ſolution of a lunar obſervation may be obtained in about one-fourth of the time required by calculation; and the anſwer, though not perfectly accurate, is ſufficiently correct for the general purpoſes of navigation.

An orthographic projection, founded on the fluxional analogies of ſpheric triangles, has been deviſed by Dr. Kelly, and publiſhed in his Introduction to Spherics and Nautical Aſtronomy, where an inveſtigation of its principles is given (p. 195, edit. 2 and 3.) with a demonſtration,

ſtration, ſhewing, that in all proper altitudes it will give the true diſtance within a few ſeconds. The ſimplicity of this projection is extremely curious, as giving an approximate ſolution of a complicated problem, by drawing four right lines only from the ſcale of chords, and it muſt therefore be very uſeful where great expedition is required.

Lunar *Rainbow*. See Rainbow.

Lunar *Year*, conſiſts of three hundred and fifty-four days, or twelve ſynodical months. See Year.

In the firſt ages, the year uſed by all nations was lunar; the variety of courſe being more frequent in this planet, and of conſequence more conſpicuous, and better known to men than thoſe of any other. The Romans regulated their year, in part, by the moon, even till the time of Julius Cæſar: the Jews too had their lunar months. Some rabbins pretend, that the lunar month did not commence till the moment the moon began to appear; and that there was a law, which obliged the perſon who diſcovered her firſt, to go and inform the ſanhedrim thereof. Upon which the preſident ſolemnly pronounced the month begun, and notice was given of it to the people by fires lighted on the tops of mountains. But this appears ſomewhat chimerical.

LUNARE Os, in *Anatomy*, one of the bones of the carpus. See Extremities.

LUNARIA, in *Botany*, elegantly ſo named by the older botaniſts and by all ſucceeding ones, from *luna*, the moon; on account of the ſilvery ſemi-tranſparent aſpect, and broad orbicular ſhape, of its ſeed-veſſels. Honeſty or Sattin-flower. Linn. Gen. 337. Schreb. 440. Willd. Sp. Pl. v. 3. 476. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 2. 385. Juſſ. 239. Tourn. t. 105. Lamarck Illuſtr. t. 561. Gærtn. t. 142, *rediviva*.—Claſs and order, *Tetradynamia Siliculoſa*. Nat. Ord. *Siliquoſæ*, Linn. *Cruciferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, oblong, of four ovate-oblong, obtuſe, cohering, deciduous leaves, of which two oppoſite ones are gibbous and pouched at the baſe. *Cor.* cruciform, of four equal, large, undivided, obtuſe petals, as long as the calyx, each tapering down into a claw of the ſame length. *Stam.* Filaments ſix, awl-ſhaped, about the length of the calyx, two of them rather ſhorter; anthers erect, or ſlightly ſpreading. *Piſt.* Germen ſtalked, ovate-oblong, compreſſed; ſtyle ſhort, permanent; ſtigma obtuſe, undivided. *Peric.* Pouch elliptical, compreſſed quite flat, undivided, erect, very large, ſtalked, terminated by the ſtyle, of two cells and two valves; the partition flat, parallel and equal to the valves. *Seeds* ſeveral, projecting into the middle of the pouch, kidney-ſhaped, compreſſed, bordered, ſupported by long thread-ſhaped ſtalks, inſerted into the lateral ſutures.

Eſſ. Ch. Pouch undivided, elliptical, flat, ſtalked; valves equal and parallel to the diſſepiment, flat. Calyx-leaves bagged at the baſe.

1. L. *rediviva*. Perennial Honeſty. Linn. Sp. Pl. 911. (L. græca perennis; Beſl. Eyſt. vern. ord. 1. t. 21. f. 1. Viola lunaris, longioribus ſiliquis; Ger. em. 464. f. 2.)—Leaves doubly and ſharply toothed. Pouches elliptic-lanceolate, acute at each end.—Native of Germany, Switzerland, and Greece. In our gardens it flowers in May or June; and is perennial, but by no means common. The *ſtems* are three or four feet high, erect, round, leafy. *Leaves* on long ſtalks, heart-ſhaped, pointed, nearly ſmooth, doubly, ſharply and finely toothed; the lower ones oppoſite, the reſt alternate. *Flowers* numerous, large, corymboſe, fragrant, crimſon. *Pouch* two inches long and not one broad, elliptical, making a ſharp angle at each extremity, green or browniſh.

2. L. *annua*. Annual Honeſty. Linn. Sp. Pl. 911. Mill. Illuſtr. t. 54. (Viola lunaris, ſive Bolbonac; Ger. em. 464. f. 1.)—Leaves ſimply and bluntly toothed. Pouch elliptical, ſomewhat orbicular, rounded at each end.—Native of Germany and Switzerland; very common in gardens, flowering in May and June. The *root* is annual or rather biennial, tapering. *Stem* ſolitary, branched. *Leaves* with much broader and leſs taper teeth than in the former, in a ſimple ſeries only. *Flowers* copious, large, ſcentleſs, crimſon. *Pouch* glaucous, ſcarcely more than an inch long, and nearly as broad, being almoſt orbicular, rounded at each end.

Linnæus having founded his ſpecific differences of theſe plants on the oppoſite or alternate ſituation of their leaves, in which reſpect they both vary, has led ſome to ſuppoſe they were both the ſame. Nothing however can be more diſtinct than the ſhape of their ſeed-veſſels, to which we have added the different manner in which their leaves are toothed. They alſo permanently differ as to duration.

Willdenow charges Gærtner wrongfully with figuring the pouch of *L. rediviva* for *Ricotia*; the latter differs in not being elevated on a ſtalk above the baſe of the flower, which ſtalk in the ſaid *Lunaria* is an inch long, or more. *Ricotia* is obſerved by Mr. R. Brown, as well as by Gærtner, to have, ſometimes at leaſt, two cells.

L. *annua* was diſcovered wild in Switzerland by M. Schleicher, though Haller ſeems not to have been aware of it.

Lunaria, in *Gardening*, compriſes plants of the herbaceous, annual, and perennial kinds, of which the ſpecies cultivated are, the perennial honeſty (L. rediviva); the annual honeſty, moor-wort, or ſatin-flower (L. annua); and the Egyptian honeſty (L. Egyptiaca.)

In the ſecond ſort the ſeed-veſſels, when fully ripe, become tranſparent, and of a clear ſhining white, like ſatin; whence the name of ſatin flower.

Method of Culture.—Theſe plants may be raiſed by ſowing the ſeed in a ſhady border, or, which is better, in patches in the ſituations where they are to remain, in the autumn, keeping the plants afterwards properly thinned out and free from weeds. They may likewiſe be ſown in the early ſpring; but the former is the better ſeaſon, as the plants riſe ſtronger. The laſt ſort ſhould have an open ſituation. When ſown in beds, the perennial ſort ſhould be ſet out where they are to remain, in the following autumn after being ſown.

Theſe plants all afford ornament and variety in the borders and clumps of pleaſure-grounds, in which the firſt ſort ſhould be placed more backward.

Lunaria, in *Ichthyology*, a ſpecies of *Perca*; which ſee.

Lunaria, in *Natural Hiſtory*, is alſo uſed by ſome authors for the ſelenites.

LUNARIS Cochlea, the name of a genus of ſhells of the ſnail-kind, according to the claſſification of ſome writers, the diſtinguiſhing character of which is their having a perfectly-round mouth. Theſe are univalve, umbilicated ſhells, with a depreſſed clavicle, and a ſurface ſometimes ſmooth, but more frequently ſtriated, furrowed, laciniated, or covered with tubercles.

It is ſaid, that Archimedes took the invention of the ſcrew, ſo famous ever ſince his time, and ſtill called after his name, from the form of this ſhell; and it is generally allowed, that architects have taken the hint of their winding flights of ſtairs from it. See Trochus, Helix, &c. under Conchology.

LUNAS, in *Geography*, a town of France, in the department of the Herault, and chief place of a canton, in the diſtrict of Lodéve. The place contains 1296, and the canton 6122 inhabitants, on a territory of 292½ kiliometres, in 12 communes.

LUNATI, Carlo Ambrosio, in *Biography*, of Milan, ſurnamed *Il Gobbo della Regina*, who came to England in the reign of James II. Lunati was a moſt celebrated performer on the violin, and Geminiani's firſt maſter on that inſtrument.

LUNATIC, Lunaticus, a perſon ſuppoſed to be affected, or governed by the moon. Hence, epileptics were anciently called lunatici, becauſe the paroxyſms of that diſeaſe ſeemed to be regulated by the changes of the moon. Thus Galen, (De Diebus Criticis, lib. iii.) ſays, the moon governs the periods of epileptic caſes: and others referred the diſeaſe entirely to this planet. Aretæus de Diuturnis Morbis, lib. i. cap. 4. See Mead's Treatiſe concerning the Influence of the Sun and Moon upon the Human Bodies, p. 38. 46, &c.

Mad people are ſtill called lunatics, from an ancient but now almoſt exploded opinion, that they are much influenced by that planet. A much ſounder philoſophy hath taught us, that if there be any thing in it, it muſt be accounted for, not in the manner the ancients imagined, nor otherwiſe than what the moon has in common with other heavenly bodies, occaſioning various alterations in the gravity of our atmoſphere, and thereby affecting human bodies. However, there is conſiderable reaſon to doubt the fact; and it is certain that the moon has no perceivable influence on our moſt accurate barometers.

A lunatic, in the contemplation of the law, is properly a perſon who hath lucid intervals; ſometimes enjoying his ſenſes, and ſometimes not. See Non-compos.

The ſtat. 17 Edw. II. cap. 10. ordains, that the king is to provide that the lands of lunatics be ſafely kept, and they and their families maintained by the profits, and the reſidue ſhall be kept for their uſe, and be delivered to them when they come to their right mind; the king taking nothing to his own uſe; and if the parties die in ſuch ſtate, the reſidue ſhall go to their executors or adminiſtrators. A warrant is now iſſued by the king, under his royal ſign manual, to the lord chancellor, or lord keeper, or lords commiſſioners for the cuſtody of the great ſeal, to perform this office for him. All matters, therefore, touching lunatics, are within the peculiar juriſdiction of the court of chancery.

Lunatics are not legally accountable for any crimes they commit in this ſtate. (1 Hawk. c. 1.) And alſo, if a man in his ſound memory commits a capital offence, and before arraignment for it he becomes non-compos, he ought not to be arraigned for it; and if, after he has pleaded, the priſoner becomes mad, he ſhall not be tried: if, after he be tried and found guilty, he loſes his ſenſes before judgment, judgment ſhall not be pronounced: and if, after judgment, he becomes of non-ſane memory, execution ſhall be ſtayed.

By the common law, if it be doubtful whether a criminal, who at his trial is in appearance a lunatic, be ſuch in truth or not, it ſhall be tried by an inqueſt of office, to be returned by the ſheriff; and if it be found by them, that the party only feigns himſelf mad, and he ſtill refuſe to anſwer, he ſhall be dealt with as if he had confeſſed the indictment. 1 Hawk. c. 1. ſ. 4.

By 39 and 40 Geo. III. c. 94.; in all caſes, where it ſhall be given in evidence upon the trial of any perſon for treaſon, murder, or felony, that ſuch perſon was inſane at the time when the offence was committed, and ſuch perſon ſhall be acquitted, the jury ſhall be required to find ſpecially, whether they acquitted him on account of inſanity; and if they do ſo find, the court ſhall order ſuch perſon to be kept in ſtrict cuſtody in ſuch place, and in ſuch manner as to them ſhall ſeem fit, until his majeſty's pleaſure ſhall be known; whereupon his majeſty may give ſuch order for the ſafe cuſtody of ſuch perſon during his pleaſure in ſuch place and manner as to his majeſty ſhall ſeem fit.

When any perſon, who ſhall be indicted for any offence, and upon arraignment ſhall be found by the jury to be inſane, ſo that he cannot be tried, or when upon the trial he ſhall be found to be inſane, the court may record ſuch finding, and order the party to be kept in ſtrict cuſtody until his majeſty's pleaſure ſhall be known; and if any perſon, charged with any offence, ſhall be brought before any court to be diſcharged for want of proſecution, and ſuch perſon ſhall appear to be inſane, the court may order a jury to be impanelled to try the ſanity of ſuch perſon; and if the jury find him to be inſane, the court may order ſuch perſon to be kept in ſtrict cuſtody, &c.; and in all caſes of inſanity his majeſty may give ſuch order, &c. as ſtated above.

And for the better prevention of crimes being committed by perſons inſane, if any perſon ſhall be diſcovered and apprehended under circumſtances that denote a derangement of mind, and a purpoſe of committing ſome crime, for which if committed he would be liable to be indicted, any juſtice, before whom ſuch perſon ſhall be brought, may, if he think fit, iſſue a warrant for committing ſuch perſon as dangerous, and ſuſpected to be inſane, ſuch cauſe of commitment being plainly expreſſed in the warrant; the perſon ſo committed ſhall not be bailed, except by two juſtices, one whereof ſhall be the juſtice who iſſued ſuch warrant; or by the quarter ſeſſions, or by one of the judges.

By 17 Geo. II. c. 5. it is enacted, that whereas there are ſometimes perſons, who by lunacy or otherwiſe are furiouſly mad, or are ſo far diſordered in their ſenſes, that they may be dangerous to be permitted to go abroad, it ſhall therefore be lawful for two or more juſtices, where ſuch lunatic or mad perſon ſhall be found, by warrant directed to the conſtables, churchwardens, and overſeers of the place, or ſome of them, to cauſe ſuch perſon to be apprehended, and kept ſafely locked up in ſome ſecure place within the county or precinct, as ſuch juſtices ſhall under their hands and ſeals direct and appoint, and (if ſuch juſtices find it neceſſary) to be there chained, if the ſettlement of ſuch perſon ſhall be within ſuch county or precinct.

And if ſuch ſettlement ſhall not be there, then ſuch perſon ſhall be ſent to his ſettlement by a vagrant paſs (*mutatis mutandis*); and ſhall be locked up or chained by warrant of two juſtices of the county or precinct to which ſuch perſon is ſo ſent in manner aforeſaid.

And the reaſonable charges of removing, and of keeping, maintaining, and curing ſuch perſons, during ſuch reſtraint (which ſhall be during ſuch time only as ſuch lunacy or madneſs ſhall continue) ſhall be ſatisfied and paid (ſuch charges being firſt proved upon oath) by order of two juſtices, directing the churchwardens or overſeers, where any goods, chattels, lands, or tenements of ſuch perſon ſhall be, to ſeize and ſell ſo much of the goods and chattels, or receive ſo much of the annual rents of the lands as is neceſſary to pay the ſame; and to account for what is ſo ſeized, ſold, or received, to the next quarter ſeſſions: but if ſuch perſon hath not an eſtate to ſatisfy the ſame, over and above what ſhall be ſufficient to maintain his family, then ſuch charges ſhall be paid by the pariſh, town, or place to which ſuch perſon belongs, by order of two juſtices, directed to the churchwardens or overſeers for that purpoſe.

Provided, that any perſon aggrieved by any act of ſuch juſtices out of ſeſſions may appeal to the next ſeſſions, giving reaſonable notice; whoſe order therein ſhall be final.

And nothing herein ſhall reſtrain or abridge the power of the king or lord chancellor; nor ſhall reſtrain or prevent any friend from taking them under their own care and protection.

But the above parts of the act relate to vagrant lunatics only, who are ſtrolling up and down the country, and do not extend to perſons, who are of rank and condition in the world, and whoſe relations can take care of them properly by applying to the court of chancery. 2 Atk. Rep. 52. See MADHOUSES.

When a perſon is legally found to be *non-compos*, (ſee NON-COMPOS,) the lord chancellor uſually commits the care of his perſon, with a ſuitable allowance for his maintenance, to ſome friend, who is then called his *committee*, which ſee. However, to prevent ſiniſter practices, the next heir is ſeldom permitted to be this committee of the perſon; becauſe it is his intereſt that the party ſhould die. But it hath been ſaid, there lies not the ſame objection againſt his next of kin, provided he be not his heir; for it is his intereſt to preſerve the lunatic's life, in order to increaſe the perſonal eſtate by ſavings, which her or his family may be hereafter entitled to enjoy. (2 P. Wms. 638.) The heir is generally made the manager, or committee of the eſtate, it being clearly his intereſt by good management to keep it in condition; accountable, however, to the court of chancery, and to the *non-compos* himſelf, if he recovers; or otherwiſe, to his adminiſtrators. In this care of idiots and lunatics, the civil law agrees with ours; by aſſigning them tutors to protect their perſons, and curators to manage their eſtates. But in another inſtance the Roman law goes much beyond the Engliſh. For, if a man by notorious prodigality was in danger of waſting his eſtate, he was looked upon as *non-compos*, and committed to the care of curators or tutors by the prætor. And by the laws of Solon ſuch prodigals were branded with perpetual infamy. But with us, when a man on an inqueſt of idiocy hath been returned an *unthrift* and not an *idiot*, (which ſee,) no further proceedings have been had. Bro. Abr. tit. Idiot 4.

By 29 Geo. II. c. 31, a lunatic may ſurrender a leaſe in the court of chancery or exchequer, in order to renew the ſame. Alſo, by direction of the lord chancellor, he may accept a ſurrender of ſuch leaſe, and execute a new one. 11 Geo. III. c. 20.

By 43 Geo. III. c. 75. whereas great injury frequently happens to perſons found lunatic or of unſound mind, and incapable of managing their affairs, and the creditors of ſuch perſons are delayed in obtaining payment of their demands for want of ſufficient power to apply the property of ſuch perſons in diſcharge of their debts and engagements, it is enacted that it ſhall be lawful for the lord chancellor, lord keeper, or lords commiſſioners for the cuſtody of the great ſeal, to order the freehold and leaſehold eſtates of ſuch perſons reſpectively to be ſold, or charged by way of mortgage or otherwiſe, for raiſing ſuch ſum of money as ſhall be neceſſary for payment of the debts, and for performing the contracts or engagements of any ſuch perſons reſpectively, and [of] the coſts and charges attending the ſame, and attending ſuch ſale or incumbrance reſpectively, and to direct the committee or committees of the eſtate of ſuch perſons reſpectively to execute in the name and on behalf of ſuch perſons conveyances of the eſtates ſo to be ſold or incumbered, and to procure ſuch admittance to and make ſuch ſurrenders of the copyhold eſtates of ſuch perſons found lunatic or of unſound mind, and to do all ſuch acts as ſhall be neceſſary to effectuate the ſame in ſuch manner, as ſuch chancellor, &c. ſhall direct; which conveyances ſhall be as good in law, as if the ſame had been executed by every ſuch perſon when in his or her ſound mind.

And in caſe of any ſurplus of money to be raiſed by any ſuch ſale as aforeſaid, after anſwering the purpoſes aforeſaid, the ſame ſhall be applied in the ſame manner as the eſtate ſold would have been applied, if this act had not been made.

And whereas many ſuch perſons may be ſeiſed and poſſeſſed of freehold and copyhold lands, &c. either for the term of their natural lives or for ſome other eſtate, with power of granting leaſes and taking fines; reſerving ſmall rents on ſuch leaſes for one, two, or three lives, in poſſeſſion or reverſion, or for ſome number of years determinable upon lives, or for terms of years abſolutely; be it enacted, that in every ſuch caſe every power of leaſing ſuch lands, &c. which is or ſhall be veſted in ſuch perſon, having a limited eſtate only, ſhall and may be executed by the committee or committees of the eſtate of ſuch perſon, under the direction and order of the lord chancellor, lord keeper, or lords commiſſioners; and ſuch leaſe or leaſes ſhall be as good in law, as if the ſame were executed by the ſaid perſon in his or her ſound mind.

And whereas perſons ſo found lunatic or of unſound mind may be ſeiſed or poſſeſſed of, and entitled to freehold or copyhold eſtates, in fee or in tail, and an abſolute intereſt in leaſehold eſtates, and it may be for their benefit that leaſes or under leaſes ſhould be made of ſuch eſtates for terms of years, and eſpecially to encourage the erection of buildings thereon, or repairing buildings actually being thereon, or otherwiſe improving the ſame; be it enacted, that it ſhall be lawful for the lord chancellor, &c. to order and direct a committee or committees of the eſtate of ſuch lunatic to make ſuch leaſes of the freehold, copyhold, or leaſehold eſtates of ſuch perſons reſpectively, according to his or her intereſt therein, and to the nature of the tenures of ſuch eſtates, for ſuch term or terms of years, and ſubject to ſuch rents and covenants, as the lord chancellor, &c. ſhall direct; and that every ſuch leaſe ſhall be as good in the law, as if the ſame had been executed by ſuch perſons in his or her ſound mind.

Every act to be done by ſuch committee or commitees by virtue of this act, and the order of the lord chancellor, &c. ſhall be as valid and binding againſt the ſaid perſons ſo found lunatic and of unſound mind reſpectively, and all perſons claiming by, through, or under him or her reſpectively, as if the perſons ſo found lunatic or of unſound mind reſpectively had been in his or her ſound mind, and had perſonally done ſuch act or acts reſpectively.

Provided nevertheleſs, that nothing herein ſhall extend to ſubject any part of the freehold, copyhold, or leaſehold eſtates of any perſon found lunatic or of unſound mind, to the demands of his creditors, otherwiſe than as the ſame are now ſubject by due courſe of law; but only to authoriſe the lord chancellor, lord keeper, or lords commiſſioners for the cuſtody of the great ſeal of the united kingdom and of Ireland reſpectively, being intruſted by virtue of the king's ſign manual with the care and commitment of the cuſtody of the perſons, and eſtates of perſons ſo found lunatic or of unſound mind, to make order in ſuch caſes as are hereinbefore mentioned, when the ſame ſhall be deemed for the benefit of ſuch perſon ſo found lunatic or of unſound mind, and incapable of managing his or her affairs.

To make a will, it is not ſufficient that the teſtator have memory to anſwer to familiar and uſual queſtions, but he ought to have a diſpoſing memory, ſo as to be able to make a diſpoſition of his eſtate, with underſtanding and reaſon.

For the marriage of lunatics, ſee Marriage.

For lunatic aſylums, ſee Mad-houses.

LUNATION, the period, or ſpace of time, between one new moon and another; alſo called *ſynodical month.* See Cycle and Epact.

LUNAWARA, in *Geography*, a town of Hindooſtan, in Guzerat; 50 miles E. of Amedabad.

LUND, a town of Sweden, in Weſt Gothland, on the Wenner lake; 36 miles N.N.E. of Uddevalla.

Lund, or *Lunden*, the moſt ancient town of Sweden, the capital of Scania, Schonen, or Skonen, of which a proverb is recorded, *viz.* that when our Saviour was born, Lund was in its glory. Lund contains ſcarcely more than 800 inhabitants, carries on but little trade, and is principally ſupported by the univerſity eſtabliſhed by Charles XI., and called, from the name of its founder, "Academia Carolina Gothorum." When Mr. Coxe viſited Sweden, it had 21 profeſſors and 300 ſtudents. The library contains 20,000 volumes. The botanical garden was not in a flouriſhing ſtate, the number of plants not exceeding 1200. Linnæus was matriculated at this univerſity. (See Linnæus.) At Lund was inſtituted, in 1776, a Royal Phyſiographical Society, which was incorporated by the king in 1778. The ſubjects treated of in its acts relate only to natural hiſtory, chemiſtry, and agriculture. Lund is an archbiſhopric. The cathedral is an ancient irregular building, raiſed at different intervals; 21 miles E. of Copenhagen. N. lat. 55° 44′. E. long. 13°.

LUNDA, a town of Sweden, in Sudermanland; 10 miles W. of Nykoping.

LUNDBY, a town of Norway, in the province of Aggerhuus, on the Glomme; 60 miles N.E. of Chriſtiania.

LUNDE, a town of Norway, on a lake of the ſame name; 28 miles W.N.W. of Chriſtianſand.—Alſo, a town of Norway; 17 miles N.W. of Skeen.

LUNDEN, a town of the duchy of Holſtein; 24 miles W. of Rendſborg.

LUNDO, a town of Sweden, in the government of Abo; 8 miles N.E. of Abo.

LUNDRESS, in our *Old Writers*, a ſterling ſilver penny; which had its name from being coined only in London, and not at the country mints.

LUNDSAY, in *Geography*, a town of Pegu, on the W. ſide of the river Ava; 60 miles W.N.W. of Pegu. N. lat. 18° 30′. E. long. 95° 43′.

LUNDSJE, a town of Perſia, in the province of Lariſtan, on the Perſian gulf. N. lat. 26° 38′. E. long. 54° 36′.

LUNDSKORON, a town of Poland; 18 miles S. of Cracow.

LUNDY Island, is ſituated in the mouth of the Briſtol channel, nearly four leagues from the coaſt of Devonſhire, England. It is rather more than three miles in length, and about one in breadth; contains about 2000 acres; and is environed by high and ſteep rocks, which render it inacceſſible, except in one or two places. The only ſafe landing place is on the eaſt ſide; where a ſmall beach admits a ſecure approach, and is ſheltered by a detached portion of rock, called the Iſle of Rats, from the great number of thoſe animals which burrow here. On landing, viſitors are obliged to climb over various craggy maſſes, before they can reach the ſteep and winding tract that leads to the ſummit, which commands views of the Engliſh and Welſh coaſts. About 400 acres only of this iſland are in cultivation; of which 300 are arable, and the reſt paſture: wheat is the chief produce. The elevated ſituation of the land, in ſome places 800 feet above the ſea, and the violence of the N.E. winds, prevent any trees from growing, though a conſiderable expence has been incurred in planting. Rabbits and rock birds are numerous; and in the ſeaſon, lobſters, crabs, and other fiſh may be obtained in abundance. About 400 head of ſheep, and 80 of cattle, are fed here; but the former do not thrive. The incloſures are ſtone fences. Of the hiſtory of the iſland but little is known. Riſdon relates that one Moriſco, who had conſpired to kill king Henry III., retired hither, and turning pirate, committed great depredations; on which the king arreſted, and had him executed on an elevated part. About the middle of the laſt century, it was purchaſed of government by a nobleman, who entruſted it to the care of a perſon named Benſon, a notorious ſmuggler, who carried on a conſiderable illicit traffic. The next proprietor of the iſland was ſir John Borlaſe Warren, who, about the year 1781, ſold it to John Cleveland, eſq.; but it appears to have been recently re-purchaſed by government. The whole rent is but 70*l.* *per annum;* no taxes are paid; nor can it maintain any revenue officer, the duties in ſeven years ſcarcely amounting to five pounds. The number of houſes is only ſeven; the inhabitants, in the year 1794, were but twenty-three. The population of the iſle was probably greater at ſome diſtant period, as many human bones have been ploughed up; and Camden ſays, "the furrows ſhow it to have been once cultivated." The chief antiquities are, the ruins of St. Anne's chapel, and what is termed Moriſco's caſtle. The latter is near the ſouth-eaſt end, and was ſtrongly fortified with large out-works and a ditch; a few old diſmounted cannon occupy the battlement, beneath which is a curious cavern. In the reign of Charles I. lord Say and Seale held the caſtle for the king; and in the time of William and Mary, the French ſurpriſed it by a ſtratagem, plundered it, and kept poſſeſſion for ſome time. Beauties of England and Wales, vol. iv.

LUNE, in *Fortification.* See Demi-lune and Lunette.

Lune, or *Lugne*, in *Geography*, a river of England, which riſes in the county of York, and runs into the Iriſh ſea, a few miles below Lancaſter. N. lat. 53° 57′. W. long. 2° 49′.

LUNE, Lunula, in *Geometry*, is the ſpace included between the arcs of two unequal circles, forming a ſort of creſcent, or half-moon, the area of which may in many caſes be as accurately determined as that of any rectilineal figure. The lune was the firſt curvilineal ſpace of which the quadrature was aſcertained, and this is ſaid to have been firſt effected by Hippocrates of Chios, though others ſay it was diſcovered by Œnopidas of Chios. However this may be, the former geometer has generally had the honour of the diſcovery attributed to him, and the figure ſtill bears his name, being commonly denominated the lune of Hippocrates, the conſtruction of which is as follows.

On the diameter of a ſemicircle (*Plate* X. *Geometry, fig.* 2.) deſcribe a right-angled triangle, of which the angular point will neceſſarily fall in the circumference. Then on each of the ſides A D, D B, deſcribe a ſemicircle, and the two figures A G F D, D H E B will be lunes, and the area of them will be equal to the area of the right-angled triangle A D B. For circles, and conſequently ſemicircles, being to each other as the ſquares of their diameters; and ſince $AB^2 = AD^2 + DB^2$; therefore the ſemicircle $ADB = AGD + DHB$; from theſe equal ſpaces taking away the common ſegments A F D and D E B, there remain the two lunes equal to the triangle A D B; and therefore, if the two ſides A D, D B, become equal, as in *fig.* 3, the two lunes are each equal to half that triangle, and conſequently the quadrature of them is determined, being each equal to a given rectilineal figure; and this is what is properly called the lune of Hippocrates, and it was the only one of which he could determine the area, for though he, in all caſes, had the meaſure of the ſpace of both together, yet it was only in the caſe of equality that he could find the area of the ſingle lune, though he could always determine a lune that ſhould be equal to any given rectilineal ſpace. For in *fig.* 3, the arc D E B is a quarter of a circle to the radius C B, and D H B is a ſemicircle. If, therefore, we conſtruct the iſoſceles right-angled triangle B C A, (*fig.* 3.) equal to any given ſpace, and on A B deſcribe the ſemicircle B D A, and from C as a centre, and with C A as a radius, deſcribe the quadrant B E A, we ſhall have the lune B D E A equal to the given ſpace as required. This, as we have obſerved above, was the firſt inſtance of the quadrature of a curvilineal ſpace, that is, of its being ſhewn equal to a rectilineal figure; for, properly ſpeaking, it is not abſolutely a quadrature, as was that of Archimedes, when he demonſtrated that every parabola was two-thirds of its circumſcribing rectangle; Hippocrates arriving at his reſult only ſtep by ſtep, by ſubtracting equal quantities from equal ſpaces, and hence finally, as by chance, coming to a caſe in which a curvilineal area is equal to a rectilineal one.

This diſcovery of Hippocrates, it ſeems, inſpired him with great confidence of being able to find the meaſure of the circle itſelf; and the reaſoning which has been attributed to him on this ſubject, though very erroneous, is ſtill extremely plauſible. Hippocrates ſuppoſed a ſemicircle A D E B (*fig.* 4.) in which he drew the three chords or radii A D, D E, E B, and on each of theſe chords he deſcribed a ſemicircle and a fourth, as F, equal to them. Then the four ſemicircles A G D, D E H, E I B, and F, being each equal to a quarter of the ſemicircle A D E B, they are therefore together equal to it, and taking away from each the ſmall ſegments A G D, D H E, E I B, we ſhall have on one ſide the rectilineal figure A D E B, equal to the three lunes, together with the ſemicircle F. If, therefore, the area of the lunes be taken away from the rectilineal A D E B, there will remain the area of the ſemicircle F, equal to a given rectilineal ſpace. This reaſoning, however, though ingenious, is ſtill very defective, in conſequence of the lunes employed in this caſe being different from thoſe of which Hippocrates had found the quadrature, for that, as we have ſeen, is bounded by a quadrant of one circle, and the half of another, whereas thoſe in the above figure are bounded by a ſemicircle, and the ſixth part of another circle, which is very different from the former, and the quadrature of it equally as difficult as that of the circle itſelf. All, therefore, that Hippocrates could draw from his inveſtigation, was merely this, that if any geometer ſhould be able to find the area of thoſe lunes, the quadrature of the circle would neceſſarily follow, and as this problem was not at that time thought ſo difficult as it is now known to be, it is not improbable that conſiderable hopes of ſucceſs were entertained after the diſcovery which this able geometer had made of the poſſibility of ſquaring what is indeed apparently a more complex figure than the circle. In fact the quadrature of the circle might be accompliſhed, if we only knew the ratio of the two lunes, deſcribed as in *fig.* 3; for then knowing the ſum of the two, and their ratio, it is obvious that we ſhould have the real area of each, and conſequently, by taking A D equal to the radius B C, the area of the circle would follow, as we have ſhewn above.

But though Hippocrates and the ancient geometers were unable to ſquare any other lune, except that above-mentioned, yet the moderns have found ſeveral other caſes in which the quadrature may be obtained, as alſo certain portions of them cut off by right lines, drawn in certain directions. In the lune of Hippocrates, the radii of the bounding circles are to each other in the ratio of two to one; but if the two circles are to each other as three to one, or as three to two, or as five to one, or five to three, they may alſo be ſquared, or may be conſtructed equal to given ſpaces, by means of the ſimple elements of geometry; but other ratios, as four to one, ſix to one, ſeven to one, &c. require the aſſiſtance of the higher geometry, being of a ſimilar deſcription of problems to thoſe of triſecting an angle, doubling a cube, &c.; and can only be ſolved by the ſame means.

We ſhall take this opportunity of giving a ſummary of ſome of the moſt curious obſervations, added by modern geometers to the diſcovery of Hippocrates.

1. If from the centre F, (*fig.* 5.) there be drawn any ſtraight line whatever F E, cutting off the portion of the lune A E G A, that portion will be quadrable, and equal to the rectilineal triangle A H E. For it may be readily demonſtrated, that the ſegment A E will be equal to the ſemi-ſegment A G H.

2. From the point E, if E I be let fall perpendicularly on A C, and F I and E F be drawn, the ſame portion of the lune A E G A will be equal to the triangle A F I. For it may be eaſily demonſtrated, that the triangle A F I is equal to the triangle A H E.

3. The lune, therefore, may be divided in a given ratio, by a line drawn from the centre F; nothing more being neceſſary than to divide the diameter A C in ſuch a manner, that A I ſhall be to C I in that ratio; to raiſe E I perpendicular to A C, and to draw the line E F: then the two ſegments of the lune A G E and G E C will be in the ratio of A I to C I.

All theſe remarks were firſt made by M. Artus de Lionne, biſhop of Gap, who publiſhed them in a work, entitled "Curvilineorum Amænios Contemplatio," 1654, 4to., and afterwards the following were added by other geometers.

4. If two circles, forming the lune of Hippocrates, be completed, the reſult will be another lune, which may be called the *conjugate* to the former, and in which mixtilineal ſpaces may be found, which may be ſquared as in the preceding caſes.

From the point F, if there be drawn any radius F M, interſecting the two circles in R and M, we ſhall have the mixtilineal ſpace R A M R equal to the rectilineal triangle L A R; which can be eaſily demonſtrated; for it may be readily ſeen that the ſegment A R, of the ſmall circle, is equal to the ſemi-ſegment L A M of the greater.

6. Hence, if the diameter *m* O touch the ſmall circle in F, it follows that the mixtilineal ſpace A R F *m* A will be equal to the triangle A S F, right-angled at S, or to half the lune A G C B A. We might have added here various other properties relating to lunes and their ſegments, but our limits will not admit of it; we muſt therefore refer the curious reader to Ozanam's "Mathematical Recreations," where the ſubject is amply illuſtrated. See alſo the remarks of David Gregory, Caſwell, and Wallis, on the quadrature of the lunula, in Phil. Tranſ. N° 259, or vol. iv. p. 452, New Abridgment; and for "the dimenſions of the ſolids generated by the converſion of the lunula of Hippocrates, and of its parts about ſeveral axes, with the ſurfaces generated by that converſion," ſee De Moivre's paper in the Philoſophical Tranſactions, N° 205, or vol. iv. p. 505, New Abridgment.

LUNELLE-LA-VILLE, in *Geography*, a town of France, in the department of the Herault, and chief place of a canton, in the diſtrict of Montpellier. The place contains 4203, and the canton 9451 inhabitants, on a territory of 145 kiliometres, in 11 communes. N. lat. 43° 40'. E. long 4° 13'.

LUNEN, a town of Germany, in the county of Mark, at the conflux of the Zeſick and Lippe; 20 miles S.S.W. of Munſter. N. lat. 51° 36'. E. long. 7° 37'.

LUNENBURG, a town of Pruſſia, in the province of Natangen; 34 miles S.S.E. of Konigſberg.

Lunenburg, or *Luneburg*, a city of Weſtphalia, capital of a principality, ſituated on the Ilmenau, ſurrounded with moats and walls, fortified with towers, and containing three churches, about 1300 houſes, and 9000 inhabitants. It has alſo three hoſpitals, in each of two of which is a church. The prince's palace and the guild-hall are in the market place. The anatomical theatre was built in 1713, and an academy for martial exerciſes was founded on the ſcite of the convent of St. Michael, which was ſuppreſſed. The burghers conſiſt of four orders, the patricians, the brewers, the merchants and tradeſmen, and the artizans; and to theſe four claſſes ſome others might be added. Since the year 1639 the magiſtracy has been compoſed of one moiety of patricians, and of another of men of letters. The Salze, which is a diſtinct part of the town, encloſed by walls, has its own ſeparate magiſtracy. This town conſiſts of fifty-four ſmall houſes, ſunk in the ground, in each of which are four large leaden pans, containing brine, which is left to exhale for the manufacture of ſalt; and the ſalt water is conveyed into them by a common pipe from the ſeveral ſprings. The ſalt-houſes, being 54 in number, and containing 216 pans, which are daily boiled, and every ſalt-houſe being eſtimated at 40,000 rix-dollars, the capital of the whole Salze much exceeds two millions of rix-dollars. Of theſe ſalt-works a fifth belongs to the ſovereign's due; and the town of Luneburg pays annually to the treaſury near 6000 rix-dollars. Of late the ſalt-trade has very much declined. The exports of the town are ſalt, lime furniſhed by two rocks in its vicinity, and beer. It likewiſe carries on a trade in wax, honey, wool, flax, linen, and frize. Goods are alſo brought here from all parts of Germany, and forwarded by the Ilmenau to Hamburgh and to Lubeck. Luneburg is 36 miles diſtant S.E. from Hamburgh. N. lat. 53° 15'. E. long. 10° 36'.

Lunenburg, or Luneburg-*Zelle*, a principality of Weſtphalia, the ſoil of which is various; conſiſting of fruitful marſh-land that lies along the Elbe, the Aller, the Jetze, and ſome other ſmall rivers, other parts, amounting to upwards of 3000 acres, that are ſandy, and others that comprehend heath, turf-moors, and ſwamps. According to the diverſity of its ſoil, it produces wheat, rye, barley, oats, peaſe, buckwheat, flax, hemp, hops, garden-ſtuff, oak, beech, firs, pines, birch, and alder. The wheat differs in quantity in different diſtricts, ſome ſuper-abounding, and the others being deficient; and ſome breed but few horned cattle and horſes, whilſt they abound in others. The heaths are covered with numerous flocks of a ſmall kind of ſheep, the wool of which is long and coarſe. The culture of bees furniſhes conſiderable quantities of honey and wax. The rivers ſupply plenty of good fiſh. The river Elbe, which traverſes the E. and N. ſides of this principality, ſerves to fertilize the adjacent marſh-lands, and to afford other advantages by its fiſheries, navigation, and tolls. This principality contains three large towns, *viz.* Lunenburg, Velzen, and Zelle, with eleven ſmaller, and thirteen large villages. Its principal manufactures are thoſe of linen, cotton, cloth, ribbons, ſtockings, and hats. The king of Great Britain derived from this principality a ſeat and voice in the college of the princes of the empire, and the circle of Lower Saxony. By the peace of Tilſit, it was annexed to the new kingdom of Weſtphalia.

Lunenburg, a county of Virginia, adjoining Nottaway, Brunſwick, Mecklenburg, and Charlotte counties; about 30 miles long, and 20 broad. It contains 4505 free inhabitants, and 5876 ſlaves.—Alſo, a townſhip in Eſſex county, in Vermont, ſeated on Connecticut river, S.W. of Guildhall, and N.E. of Concord, and containing 393 inhabitants.—Alſo, a townſhip of Worceſter county, Maſſachuſetts, on an elevated ſituation, 25 miles from the Great Monadnock mountain, in New Hampſhire. It contains 14 000 acres of land, on which are 1243 inhabitants, and is more diſtinguiſhed by its ſalubrity than by its wealth. The inhabitants have little intercourſe or trade with their neighbours; but they carry on the nailing buſineſs to advantage.—Alſo, a town of New York, in Green county, now called "Eſperanza," ſituated on the W. ſide of Hudſon's river, oppoſite to the city of Hudſon, and 30 miles S. of Albany. The ſoil of this thriving village, or town, is uneven, nor is the ſoil very good.—Alſo, a county of Nova Scotia, on Mahone bay, on the S. coaſt of the province, facing the Atlantic ocean. Its chief towns are New Dublin, Lunenburg, Cheſter, and Blandford. In Mahone bay, La Have, and Liverpool, ſeveral ſhips trade to England with timber and boards.—Alſo, a townſhip in the above county, ſituated on Merliqueth, or Merliquaſh bay, well ſettled by a number of induſtrious Germans. The lands are good, and well cultivated; 35 miles S.W. by S. from Halifax.

LUNENSE Marmor, in the *Natural Hiſtory of the Ancients*, the name of that ſpecies of white marble, now known among us by the name of the Carrara-marble, and diſtinguiſhed from the ſtatuary kind by its greater hardneſs and leſs ſplendour. It was ever greatly eſteemed in building and ornamental works, and is ſo ſtill. It is of a very cloſe and fine texture, of a very pure white, and next in purity to the Parian marble. It has always been found in great quantities in Italy, and is ſo to this day. See *Carrara* Marble.

LUNES, or Lowings, in *Falconry*, leaſhes or longlaſhes to call in hawks.

LUNETTE, in *Fortification*, an inveloped counterguard, or elevation of earth, made beyond the ſecond ditch, oppoſite to the places of arms; differing from the ravelins only in their ſituation.

Lunettes are uſually made in ditches full of water, and ſerve to the ſame purpoſe as fauſſebrays, to diſpute the paſſage of the ditch.

Lunettes are placed on both ſides of the ravelin, as B, B, *Plate* VIII. *Fortification, fig.* 8. to increaſe the ſtrength of a place: they are conſtructed by biſecting the faces of the ravelin with the perpendicular L N, on which are ſet off 30 toiſes from the counterſcarp of the ditch, for one of its faces; the other face P N is found by making the ſemigorge T P of 25 toiſes; the ditch before the lunettes is 12 toiſes; the parapet three, and the rampart eight. There is ſometimes another work made to cover the ſaliant angle of the ravelin, ſuch as A, called *bonnet*, whoſe faces are parallel to thoſe of the ravelin, and when produced biſect thoſe of the lunettes; the ditch before it being 10 toiſes. There are likewiſe ſome lunettes, whoſe faces are drawn perpendicular to thoſe of the ravelin, within a third part from the ſaliant angle, and their ſemigorges are only 20 toiſes. Mr. Muller recommends the face P N to be perpendicular to that of the baſtion, which would then defend it in a direct manner; and if the ſemigorges of the bonnet A were only ſeven or eight toiſes, it would be leſs expenſive, and its ditch and the covert-way before it would be better defended by the lunettes. Elem. of Fortif. p. 36.

Lunette, in the *Manege*, is a half horſe-ſhoe, or ſuch a ſhoe as wants the ſpunge, *i. e.* that part of the branch which runs towards the quarters of the foot.

Lunette is alſo the name of two ſmall pieces of felt, made round and hollow, to clap upon the eyes of a vicious horſe that is apt to bite, and ſtrike with his fore feet, or that will not ſuffer his rider to mount him.

LUNE'VILLE, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Meurthe, ſituated between the Veſouze and the Meurthe, in a marſhy plain, which has been drained. An academy was inſtituted here by king Staniſlaus, and furniſhed with a good library. The place contains 9797, and the two cantons 22,334 inhabitants, on a territory of 345 kiliometres, in 37 communes; 13 miles E.S.E. of Nancy. N. lat. 48° 36′. E. long. 6° 34′.

LUNGKORCKE, a town of Pruſſia, in the palatinate of Culm; 10 miles N. of Straſburg.

LUNGOBARDI, in *Ancient Geography*. See Lombards.

LUNGON, in *Geography*, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 62° 40′. E. long. 17° 48′.

LUNGPOUR, a town of the country of Cachar; 15 miles E. of Coſpour.

LUNGRO, a town of Naples, in Calabria Citra, chiefly inhabited by Greeks; 10 miles S.S.W. of Caſſano.

LUNGRY, a town of Bengal; 36 miles S. of Calcutta. N. lat. 21° 58′. E. long. 87° 35′.

LUNGS, in *Anatomy* and *Phyſiology*, are organs of the body, ſituated in the cheſt, through which the blood paſſes on its courſe from the right to the left ſide of the heart, and in which it is changed from the venous to the arterial ſtate, by means of expoſure to the atmoſpherical air received into theſe organs in reſpiration.

The two lungs, (right and left,) are entirely alike in their compoſition; their ſize is conſiderable, and they conſiſt of ſeveral different tiſſues, which render their ſtructure complicated. Theſe tiſſues are almoſt all vaſcular, which gives to the lungs their characteriſtic ſpongy and ſoft nature. They poſſeſs, beſides the properties ariſing from their organization, only the inſenſible organic contractility, or tonic power. Perhaps the muſcular fibres of the air-veſſels may conſtitute an exception to this obſervation. In conſequence of their vital properties being limited to this tonic power, they are not capable of any motion in themſelves; and they therefore remain motionleſs, unleſs ſome exterior agency puts them in motion; yet, in their functions as reſpiratory organs, they exhibit a continual movement, an alternation of dilatation and contraction, by which the air is firſt received into their interior, and then expelled after a certain interval. If this be interrupted for a very ſhort time, the blood is no longer changed, the circulation ceaſes, and death follows. The lungs then require ſome auxiliary means for the execution of the functions to which they are deſtined; theſe are furniſhed by the conſiderable organs of motion ſurrounding them, which at the ſame time compoſe a ſufficiently firm defence to protect them againſt external injury. The ribs with their cartilages, the ſternum, and the dorſal vertebræ, form the ſolid part of the cavity containing the lungs; the diaphragm and intercoſtal muſcles the moveable parts: the cavity itſelf reſulting from their union, is named the thorax. To the ſides of this cavity we muſt refer the phenomena of dilatation and contraction of the lungs, which are entirely paſſive, and follow the impulſe received from this ſource. Thus the thorax conſtitutes an eſſential part of the reſpiratory apparatus.

But the thorax contains alſo the central organ of the circulation (the heart), and the large blood-veſſels connected with it; thus the apparatus of this function is brought near to, and in a manner confounded at its origin with that of reſpiration. Yet they are diſtinct, by the diſpoſition of the common cavity which contains them. For the heart occupies that part of the cheſt which is formed by the vertebral column behind, by the ſternum in front, and by the aponeurotic centre of the diaphragm below; parts which are either immoveable, or capable only of a ſmall degree of motion. The lungs, on the contrary, occupy the moſt moveable part of the cheſt; thoſe formed by the ribs and intercoſtal muſcles, and the muſcular parts of the diaphragm.

The following account of the reſpiratory apparatus will include deſcriptions, 1ſt, of the cheſt, in which the lungs are contained; 2dly, of the motions which that part is capable of; 3dly, of the membranes lining the cavities; 4thly, of the lungs themſelves; and 5thly, of their functions.

The cheſt or thorax is a conical cavity, ſlightly flattened in front, occupying the upper part of the trunk, and conſequently having a much larger ſhare of the ſkeleton below than above it. Yet, if we compare its poſition to that of the moſt important organs, we ſhall find the latter placed almoſt equally near the viſcera contained in the thorax. The parts ſituated in the head, and thoſe contained in the abdomen differ very little in their diſtance from the heart; while the latter organ is placed at very unequal diſtances from the upper and lower extremities. Hence the heart is the centre of the organs contained in the head and abdomen, while it exerts a much leſs active influence on the lower than on the upper limbs.

The cheſt is ſituated in front of the vertebral column; but the curvature of the ribs, which is very prominent behind, cauſes the cavity to paſs a little beyond the ſpine in that direction, particularly towards the middle. The plane of the front of the cheſt is poſterior to that of the front of the face; commonly it is nearly on a level with that of the abdomen; but the numerous variations of the latter cavity produce correſponding varieties in this reſpect.

A falſe idea would be formed of the cheſt by examining it when covered with ſoft parts, and articulated to the upper limbs. The numerous muſcles ſurrounding it above, the ſhoulder, and particularly the clavicle, give to its upper part an extent in the tranſverſe direction, which does not exiſt in the ſkeleton, where the cheſt repreſents a cone flattened in front and behind, with the baſis downwards and the apex upwards. The longitudinal axis of this cone is oblique from above downwards, and behind forwards; but all its ſides do not partake equally in this obliquity, which belongs only to the anterior and lateral parts: the poſterior, formed by the ſpine, has no concern in it. Hence a vertical line, drawn from the middle of the ſpace, included between the vertebral column and the enſiform cartilage, perpendicularly through the cheſt, would not paſs out at the centre of the ſuperior aperture, but would go in front of the clavicular extremity of the ſternum. The diameters, whether antero-poſterior or tranſverſe, of the cone repreſented by the cheſt, are all larger in proportion as they are nearer the baſis.

In its general capacity the cheſt holds a middle place between the head and the abdomen. Its depth, from above downwards, is much leſs in the natural ſtate, than it appears in the ſkeleton. The diaphragm below forms a conſiderable arch projecting into the cheſt, and very conſiderably leſſening its extent in this direction. But this diminution affects the middle, which is occupied by the central tendon, much leſs than the ſides. Again, the clavicles above very manifeſtly ſurmount the ſternum, and contribute to make the cheſt appear higher than it really is. The breadth is much leſs at the upper part, than it appears to be on the firſt view, becauſe the clavicle and the muſcles enlarge the exterior forms without affecting the internal dimenſions. The capacity conſtantly increaſes in proportion as we proceed downwards. Yet the habit of wearing clothes that are very tight about the waiſt, particularly ſtays, contracts that part, ſo that the cheſt is ſometimes ſhaped like a barrel, narrow above and below, and broader in the middle. The concavity in the dorſal part of the ſpine makes the cheſt more capacious in its middle; yet this enlargement is not equal to the contraction produced by the anterior prominence of the bodies of the vertebræ. In fact, the antero-poſterior diameters are all much leſs extenſive along the middle line of the cheſt than on the ſides; ſo that the ſternum is ſeparated from the ſpine by an interval much ſmaller than that which exiſts between the cartilages of the ribs and the hollows at the ſides of the ſpine.

In the female the cheſt is proportionally broader, but ſhorter than in the male.

Any cauſe of diſtention affecting the abdomen, as pregnancy, aſcites, large tumours, &c. ſtrongly elevates the cheſt, preſſes the ribs together, and diminiſhes the perpendicular axis, while the tranſverſe and antero-poſterior diameters are rather increaſed, particularly below. There are malformations of the cheſt, particularly affecting the ſternum and ribs, which diminiſh the breadth, while they leave the height nearly the ſame. Individuals prediſpoſed to phthiſis are remarkable for this tranſverſe contraction of the cavity, which makes the prominence of the ſternum very conſpicuous in front. In other inſtances the cheſt is affected, in conſequence of deformities of the ſpine: when this is curved, the ribs are brought very cloſe together on one ſide, and are proportionally ſeparated on the other, ſo that the two ſides of the cavity are rendered very unequal. The cheſt, in ſuch inſtances, is generally very prominent.

Deſcription of the particular Bones of the Cheſt.—It is compoſed of a common, and of proper parts. The dorſal portion of the ſpine is the former (ſee SPINE); the ſternum in front, and the ribs on each ſide, are the latter.

The *ſternum* is a ſymmetrical bone, placed in the front and middle of the cheſt, flattened and elongated, broad above, contracted about the middle, then again becoming a little broader, and terminating at laſt below by a prominent point. It is divided into a cutaneous and a thoracic ſurface, a clavicular and an abdominal extremity, and lateral edges.

The cutaneous ſurface is anterior, covered by the ſkin, and more immediately by the aponeuroſes of the ſterno-maſtoidei and great pectoral muſcles: it is marked ſometimes by lines dividing it into ſurfaces of unequal breadths, and correſponding to the original diviſions of the bone. It is a little convex at the upper part, and then flattened. The attachment of the muſcular fibres, and of the ligaments of the ribs, gives it a roughneſs. The thoracic ſurface is poſterior, a little concave, ſmooth, and ſometimes exhibits tranſverſe lines ſimilar to thoſe already mentioned. It correſponds above to the ſterno-hyoidei and ſterno-thyroidei; then, for a ſhort ſpace, to the cellular tiſſue of the mediaſtinum, and afterwards to the triangularis ſterni.

The clavicular extremity is the broadeſt and thickeſt part of the bone. Its middle conſiſts of a broad concavity, almoſt entirely occupied by the inter-clavicular ligament: on each ſide of this is a large ſuperficial excavation, concave from within outwards, and convex from before backwards, articulated to the clavicle, and ſurrounded by ligamentous inſertions. The abdominal extremity is called alſo the enſiform or xiphoid cartilage or appendix. It is thin, flattened, broader above, and terminating in a narrower way below. Its figure varies greatly in different individuals: the lower end ſometimes turns forwards, ſometimes backwards; occaſionally it is perforated. It generally is cartilaginous, in a greater or leſs degree, until the later periods of life. It affords inſertion to the aponeuroſes of the abdominal muſcles; the recti cover it in front, and the diaphragm behind.

The margins of the ſternum are thick, and exhibit ſeven articular cavities, to which the cartilages of the true ribs are articulated. Theſe are oblong, and not very ſmooth. The firſt, which is ſuperficial, and not clearly marked, is immediately below the concavity that lodges the clavicle. The ſucceeding ones are ſeparated by ſlight concavities correſponding to the intercoſtal ſpaces, and become nearer and nearer to each other, in proportion as they are placed lower.

The ſubſtance of the bone is almoſt entirely cellular, and its ſurfaces are covered by a very thin compact ſtratum of bony texture: hence the ſternum is very light in proportion to its ſize. It conſiſts at firſt of eight or nine pieces, encloſed in a maſs of cartilage: theſe are ſoon reduced to ſeven, and then to five; which number continues for a long time, the individual portions being ſtill ſeparated by cartilaginous ſtrata. The firſt of theſe pieces is the largeſt, and is broader above than below; the two following are nearly ſquare, and very ſhort: the fourth is longer; the laſt includes the enſiform appendix already mentioned. This diviſion no longer exiſts in the adult; the pieces are united in the following order. The ſecond is conſolidated with the third, and then the latter with the fourth: the other diviſions generally continue through life; ſo that the ſternum is ordinarily deſcribed as being compoſed of two bones and a cartilage. The firſt bone ends at the ſecond rib, which is articulated between it and the ſecond bone. The two pieces are united by a thin layer of cartilage, and their union is often conſolidated by bone. The enſiform cartilage is connected in the ſame way to the end of the ſecond bone; but after a certain age, it is generally more or leſs oſſified.

The *ribs* are bones of irregular figure, placed in ſucceſſion from above downwards, on each ſide of the cheſt, conſiſting generally, but not conſtantly, of twelve pairs, flattened and rather thin in front, rounded and thicker behind, and more or leſs arched. They differ in length, breadth, and direction. The length, which is inconſiderable in the firſt, is ſuddenly increaſed to a very conſiderable degree in the ſecond; and this augmentation proceeds gradually as far as the eighth. From this they again decreaſe, ſo that the twelfth is about as long as the firſt. The firſt rib is the broadeſt; the ſucceeding ones become narrower, but in an almoſt inſenſible degree. Each individual rib is narroweſt from its vertebral extremity to the angle: it grows broader in front of this part, and increaſes to its ſternal end. The firſt rib forms nearly a right angle with the vertebral column; the following are more and more inclined outwards and downwards, ſo that their vertebral are higher than their cartilaginous extremities. The firſt forms a ſmall, but nearly regular ſemicircle; the ſucceeding ones form leſs perfect ſegments of circles, which increaſe ſucceſſively as far as the eighth, and then decreaſe. All are more curved behind

hind than in the front: and hence ariſes the deep excavation on each ſide of the cheſt, in the former direction, for lodging the lungs. They are all twiſted on themſelves, ſo that the two extremities cannot reſt at the ſame time in an horizontal plane. The point of twiſting is at the angle, conſequently the firſt, which has no angle, does not exhibit this circumſtance, which is the more ſenſible in proportion as the angle is more ſtrongly marked. The ribs are diſtinguiſhed into two claſſes: the ſeven ſuperior ones, articulated to the ſternum, are called *true,* or thoracic; the five inferior, joined to each other in front by their cartilages, which are not connected to the ſternum, are named *falſe,* or abdominal. Each is divided into a vertebral and a cartilaginous extremity, and a body.

The vertebral extremity is poſterior and articulated to the ſpine. It exhibits a rounded and contracted neck, of about an inch in length, reſting on the tranſverſe proceſs of the correſponding vertebra. This neck is ſlightly expanded at its poſterior end, to form the head of the rib, which exhibits a cartilaginous ſurface for articulation with the vertebral column. The ſurface is rounded in its outline, ſingle in the firſt, eleventh, and twelfth ribs, which are each articulated to a ſingle body of a vertebra, and divided by a riſing line into two parts in the nine others, which are ſeverally articulated to hollows formed between two vertebræ. Of theſe two portions the lower is the largeſt.

The cartilaginous extremity is elongated from above downwards, broad and concave in the ten firſt ribs, and narrower in the two laſt. It is moſt cloſely joined to the correſponding cartilages, ſo as to appear perfectly continuous with it.

The body of the rib may be conſidered under four different points of view; *viz.* the external and internal ſurfaces, the ſuperior and inferior margins. 1. On the outſide it is convex, and preſents behind a tubercle, marking the termination of the neck, and divided into two portions: the inner of theſe is a ſmooth cartilaginous ſurface, nearly circular in its figure, articulated to the tranſverſe proceſs of the lower of the two dorſal vertebræ, between the bodies of which the head is articulated; the external is rough, and affords attachment to a ſtrong ligament. This tubercle is confounded with the angle in the firſt rib, and is deficient in the two laſt. In front of this eminence is the angle, or part at which the rib, after being continued from the vertebral column obliquely downwards and outwards, turns forwards: inſtead of being angular, as its name implies, this bend is gentle and rounded. It has a prominent oblique line, not ſeen in the firſt and twelfth, but ſlight in the ſecond and eleventh, and more ſtrongly marked and diſtant from the tubercle, in proportion as the rib is lower down: it gives attachment to the ſacro-lumbalis. Between this angle and the tuberoſity there is a ſurface directed backwards, occupied by the longiſſimus dorſi, and becoming broader as we trace the ribs from above downwards. The reſt of the rib, in front of the angle, forms a nearly ſmooth ſurface, directed upwards in the firſt, where we obſerve in it two ſuperficial impreſſions made by the courſe of the ſubclavian artery and vein, ſeparated by a ſurface, in which the ſcalenus is inſerted, and inclined more and more outwards in the ſucceeding ribs, in proportion as they are lower. In the middle of the ſecond there is a mark from the attachment of the ſerratus anticus, and on the others analogous impreſſions from various muſcles of the cheſt and abdomen, as the obliquus externus, pectoralis minor, ſerratus anticus, ſerrati poſtici, &c.

2. On the inſide the ſurface is uniformly concave and ſmooth, covered by the pleura, directed downwards in the firſt, a little inclined in the ſame direction in the ſecond, but completely internal in the remainder.

3. Above, the body of the rib forms an obtuſe margin, which is internal in the firſt, inclined upwards in the ſecond, and directly ſuperior in all the others. It affords attachment to the intercoſtal muſcles, except in the firſt rib.

4. The inferior margin is ſharp, particularly near the tubercle, and becomes more obtuſe in front. Juſt within this is found the groove of the rib, which is deep at the back part of the bone, becomes gradually ſhallower, and is inſenſibly loſt in the front. It lodges the intercoſtal nerves, but is hardly perceptible in the firſt and laſt ribs. This inferior margin affords attachment to the intercoſtal muſcles.

Theſe bones are thin in compariſon to their length, and have conſequently conſiderable elaſticity, which is not obſerved in any other part of the ſkeleton. They are compoſed moſtly of compact bone, with a little cellular ſtructure in their centre: the latter is more abundant at the anterior and poſterior extremities. They are developed at an early period in the fœtus, and are more perfect at the time of birth than any other bones, except thoſe belonging to the organ of hearing. They are formed from a ſingle point of oſſification, excepting the head, which is not conſolidated to the body till the formation of the ſkeleton is nearly complete.

Sometimes there are thirteen ribs: the thirteenth may be either above or below the ordinary ſeries.

Articulations of the Cheſt.—The cheſt, formed by bones of an arched figure, moſt of which reſt on the ſternum by one end, and by the other on the vertebræ, preſents in front and behind articulations correſponding to theſe relations. The joints, ſeparately conſidered, do not admit of much motion; but the pectoral cavity, taken altogether, enjoys an extenſive power of movement.

The poſterior Articulations of the Cheſt.—The ribs are united to the vertebræ; 1ſt, by the articular ſurfaces of their heads to the cavities in the bodies of the vertebræ, each of which cavities is formed in a ſingle vertebra for the firſt, eleventh, and twelfth, in the two adjoining bones and their connecting fibro-cartilage, for the other ribs; 2dly, by the articular ſurfaces of their tubercles to the tranſverſe proceſſes of the vertebræ, excepting the two laſt ribs, which have not this kind of articulation. The firſt has been called the coſto-vertebral; the latter the coſto-tranſverſal articulation.

The *coſto-vertebral* joints. In each of theſe the union is effected by means of an anterior and an inter-articular ligament, and two ſmall ſynovial membranes. The anterior ligament is a broad, thin, flattened, and irregularly quadrilateral fibrous faſciculus, attached in front, above and below the articular ſurface of the head of the rib, diverging towards the ſpine, and fixed by its ſuperior fibres to the body of the vertebra that forms the upper part of the correſponding cavity, by its inferior to that which forms the lower, and by the middle to the intermediate fibrocartilage. The latter are in general leſs ſenſible than the two former, each of which forms a very diſtinct faſciculus. The diſpoſition of this ligament is not exactly the ſame in the firſt, eleventh, and twelfth ribs, each of which is articulated to a ſingle vertebra; yet the fibres extend a little on the neighbouring vertebræ. It is covered in front by the great ſympathetic nerve, by the pleura, and on the right ſide by the vena azygos: it has a radiated figure, is ſhort and ſtrong, compoſed of longer ſuperficial and ſhorter deep-ſeated fibres, and has ſmall vaſcular intervals. It is applied over the joint, for which, in conjunction with the middle coſto-tranſverſal ligaments, it may be conſidered as forming a kind of fibrous capſule.

The inter-articular ligament does not exiſt in the joints of the firſt, eleventh, and twelfth ribs. It is a more or leſs thick fibrous faſciculus, of a flattened figure, fixed on one ſide to the prominent angle of the head of the rib, and on the other to the correſponding depreſſion of the cavity in which it is received. It ſeparates the two ſynovial membranes from each other, and is continuous with the fibro-cartilage, as we may perceive by ſawing the joint acroſs, ſo as to divide it into a ſuperior and an inferior half.

The ſynovial membranes are double in the joints that poſſeſs the ligament laſt deſcribed; but in the others there is only a ſingle one, covering the whole extent of the correſponding articular ſurfaces, and reflected from the one to the other. Where there are two, each capſule belongs to its correſponding upper or lower half of the articulation, and is ſeparated from the other by the inter-articular ligament. Theſe membranes are not clearly marked, do not exhibit the uſual poliſh on their ſurface, contain a remarkably ſmall quantity of ſynovia, and occupy often a very ſmall ſpace on account of the great ſize of the inter-articular ligament. The latter is ſometimes ſo thick, that it may almoſt be doubted, whether the joint poſſeſſes any ſynovial membrane; in other inſtances, however, theſe membranes are very diſtinct. Although the bones are held together almoſt as cloſely as at the anterior articulations between the cartilages and the ſternum, the joint is not ſo frequently loſt in the old ſubject. Yet anchyloſis does ſometimes occur; and this is a character diſtinguiſhing it from joints where the membrane is clearly marked, which may be anchyloſed from accident or diſeaſe, but hardly ever undergoes this change in the natural progreſs of oſſification.

The *coſto-tranſverſal* articulations are formed by a ſmall ſynovial cavity, a poſterior, a middle, and an inferior coſto-tranſverſal ligament. The latter does not belong to the tubercle and proceſs which are contiguous: but extends from the proceſs to the upper edge of the rib immediately below. The poſterior ligament ariſes from the end of the proceſs, paſſes nearly horizontally outwards, and is inſerted into the rough eminence of the tubercle of the rib. Its fibres are parallel and cloſe, form a very diſtinct faſciculus nearly quadrilateral in its figure, correſpond behind to the muſcles contained in the excavations on the ſides of the ſpinous proceſſes, and in front to the articulation. The middle ligament is a collection of irregular reddiſh fibres, rather cellular than ſtrictly ligamentous, placed between the front of each tranſverſe proceſs, and the correſponding part of the rib. When we forcibly ſeparate theſe parts, we diſtinguiſh the fibres which are torn by the ſeparation: to ſee them entire we ſhould ſaw through the proceſs and rib in their connected ſtate. The inferior ligament is a diſtinct fibrous faſciculus, compoſed of numerous ſtrong and parallel fibres. It ariſes from the root of the tranſverſe proceſs, paſſes obliquely to the upper edge of the rib immediately below, and is inſerted near the vertebral extremity. The firſt and the laſt ribs do not poſſeſs it. It is covered in front by the intercoſtal veſſels and nerves, behind by the longiſſimus dorſi: on the outſide it is continuous, by means of a thin aponeuroſis, with the intercoſtal muſcle, and it completes on the inſide a ſmall cellular ſpace traverſed by the poſterior branch of the nerves. Between this ſpace and the vertebral column there is commonly a ſmall fibrous faſciculus, ariſing from the baſis of the proceſs, and attached to the articular extremity of the rib below, where it is united to the upper part of the radiated ligament. The two cartilaginous ſurfaces, of the tranſverſe proceſs and the tubercle of the rib, are covered by a ſmall ſynovial membrane, which is looſer, contains more ſynovia, and is always more diſtinct than that of the preceding joint. Hence it never becomes anchyloſed by the mere progreſs of age.

Anterior Articulations of the Cheſt.—Theſe are not formed by the bony portions of the ribs, but by a ſeries of cartilages terminating them: the ſeven ſuperior of theſe are joined to the ſternum, while the five inferior, connected to each other, have no other kind of connection. Theſe cartilages muſt be deſcribed before we ſpeak of the articulations. They are not uniform in their length, breadth, and direction. That of the firſt rib is very ſhort; the ſucceeding ones increaſe in length as far as the laſt of the true ribs. Thoſe of the falſe ribs again become ſhorter and ſhorter, ſo that it is ſcarcely perceptible in the laſt. The firſt is the broadeſt, and they become narrower as they are placed lower down. The breadth of the two firſt is nearly uniform throughout; it diminiſhes in the others from the coſtal towards the oppoſite extremity. This diminution, however, is not regular in the ſixth, ſeventh, and eighth, which are conſiderably increaſed in breadth, where they are joined to each other. The firſt cartilage is a little oblique from above downwards; ſo that the angle formed between it and the ſternum is acute above and obtuſe below; the ſecond is nearly horizontal, and follows the ſame direction as the rib to which it belongs. The following cartilages of the true ribs are more oblique from below upwards, and more manifeſtly curved where they ariſe from the ribs in proportion as they are lower. At this curvature the ribs and their cartilages take oppoſite directions: the firſt deſcend from the ſpine, the others aſcend to the ſternum. This curvature is diminiſhed a little in the firſt of the falſe ribs, where, however, it is ſtill very conſiderable, and decreaſes ſucceſſively to the laſt, in which the cartilage follows the direction of the bone.

The general figure of the cartilages correſponds to that of the bones to which they are connected. The ſurface of the body is rather unequal externally, or on the front, ſlightly convex in moſt, covered by the pectoralis major above, by the obliquus externus and rectus below. The firſt gives attachment to the coſto-clavicular ligament. Behind or on the inſide it is ſlightly concave, and correſponds in the firſt five or ſix to the pleura and triangularis ſterni, to the tranſverſus abdominis in the ſucceeding ones. The upper edge is more or leſs concave, and the lower convex: they afford attachment to the intercoſtal muſcles, and form a continuation of the intercoſtal ſpaces, which, as well as the muſcles of the ſame name, become narrower in proportion as they are lower. Thoſe between the ſixth and ſeventh cartilages, and between the latter and the eighth, are interrupted by ſmall articulations, formed by the contiguous cartilaginous ſurfaces.

Each cartilage has an external or coſtal and an internal extremity, which may be alſo called ſternal in the ſeven firſt. The former conſiſts of a ſmall convex and unequal ſurface intimately united to the correſponding concavity in the extremity of the rib. The latter has in the true ribs a ſmall articular ſurface of a convex figure, adapted to the hollow of the ſternum, in which it is received. In the three firſt falſe ribs this extremity is elongated, ſituated immediately under the cartilage above it, and united to it: in the two laſt it is ſeparated from the cartilage above by a marked interval.

In reſpect to their ſtructure, the cartilages of the ribs have a great analogy to thoſe of the larynx. Both are very denſe and compact, exhibit, at firſt view, no marks of organization, although they poſſeſs really a peculiar ſtructure, are difficultly reduced into gelatine by boiling, and are remarkable for their tendency to oſſification. Even in ſubjects not much advanced in age, we frequently find a bony point in the centre of theſe cartilages: this is the commencement of oſſification. Thoſe of the firſt ribs undergo this change moſt readily: they are often completely bony, while the others ſtill exhibit their natural texture. This oſſification is always preceded by a yellowiſh tint, which ſucceeds to the white colour that characterizes the cartilages of the child. When they are converted into bone, they reſemble the ribs in being compact externally and cellular on the inſide. In the rib of an old perſon the cells of the rib and of its cartilage are continuous.

Articulations of the Cartilages of the true Ribs.—Each of theſe has a ſmall ſurface at its ſternal extremity, received into a correſponding hollow of the edge of the ſternum, covered by a thin layer of cartilage. The joint poſſeſſes an anterior and a poſterior ligament, and a ſynovial membrane. The ſeventh rib is moreover united by a peculiar ligament to the enſiform cartilage. The anterior ligament is thin and broad, compoſed of radiated fibres ariſing from the extremity of the cartilage, diverging as they traverſe the front of the articulation, and expanded on the front of the ſternum, where they are mixed with thoſe of the oppoſite ſide, with the perioſteum, and with the fibres of inſertion of the pectoralis major, by which this ligament is covered in front. The ſuperficial fibres are long: the more deeply-ſeated are ſhorter, and proceed directly from the cartilage to the neighbouring portion of the ſternum. They are intermixed, not only with the oppoſite fibres, but alſo with thoſe of the ligament immediately above and below. From the union of all theſe fibres a thick ſtratum is formed, covering and ſtrengthening the ſternum, and more ſtrongly marked below than above. The poſterior ligament differs from the preceding by being thinner and having its fibres leſs apparent: in other reſpects they are nearly ſimilar; that is, they proceed in a radiated manner from the cartilages to the ſternum. The fibrous ſtratum on this ſurface of the bone is as thick as on the other, but it exhibits a more uniform kind of organization. We do not ſee in it the decuſſation of numerous diſtinct faſciculi, but a ſmooth and almoſt poliſhed ſtratum, adhering very cloſely to the bone, with many of its fibres not derived from the ligaments of the ribs, but purſuing rather a longitudinal direction. The ſynovial membrane is remarkable for its ſmall extent, and for the want of poliſh on its ſurface. If we did not diſcern a ſmall quantity of ſynovia in the joint, we might be inclined to doubt the exiſtence of ſuch a membrane. In this reſpect it very much reſembles that of the coſto-vertebral articulation. In general, it is rather more looſe in the two or three lower articulations, than in the ſuperior ones. In the adult it certainly does not exiſt in the firſt: the cartilage is continuous with the bone, which explains the ſmall amount of motion, of which this rib is ſuſceptible. In the articulation of the ſecond rib there is a ſmall inter-articular ligament. A ſmall elongated and very thin fibrous faſciculus goes from the lower edge of the ſeventh rib obliquely downwards and inwards to the front of the enſiform cartilage, where it forms an angle with the ligament of the oppoſite ſide. It is covered by the rectus abdominis.

Articulations of the Cartilages of the falſe Ribs.—We have ſtated, that the neighbouring edges of the ſixth and ſeventh, and of the ſeventh and eighth cartilages, are articulated by means of oblong ſurfaces. Theſe are covered by ſynovial membranes much more apparent, more looſe, and containing more ſynovia than thoſe which are found between the ſuperior cartilages and the ſternum. Sometimes between the fifth and ſixth, more rarely between the eighth and ninth, a ſimilar articulation, and conſequently a ſimilar ſynovial membrane, are found, which manifeſtly refer only to the mobility of theſe cartilages. To maintain the cartilages of the falſe ribs in their poſitions, ſeveral ligamentous fibres, holding them ſtrongly, particularly in front, paſs from the laſt true to the firſt falſe rib; from the latter to the ſecond, and from it to the third. Theſe fibres are particularly evident in front of the ſynovial membranes which we have mentioned. Analogous fibres attach the extremity of each of the firſt three falſe cartilages to the lower portion of the cartilage immediately above it. The only connection of the two laſt is by means of the muſcles. Ligamentous fibres alſo paſs between the cartilages of the ſixth and ſeventh true ribs.

The Cheſt conſidered in general.—We ſhall arrange the deſcription of this cavity under the diviſions of its external and internal ſurface; ſuperior and inferior circumference. The external ſurface compriſes four regions; an anterior or ſternal, a poſterior or vertebral, and two lateral or coſtal. The anterior is the narroweſt, more or leſs flattened or projecting in different ſubjects, and according to the prevalence of certain prediſpoſitions. In the middle we have the cutaneous ſurface of the ſternum, on the ſides the cartilages of the true ribs, and a ſeries of lines, which indicate in each rib the point of its union with the correſponding cartilage. This ſeries may be conceived as united into one general line, running obliquely from above downwards and from within outwards, forming the lateral boundary of the anterior region, which, from this particular diſpoſition, is much broader below than above. Between theſe cartilages broad intervals appear in the firſt true ribs, narrower ones in the laſt: they are ſtill more narrowed in the firſt falſe ribs, but grow broader again in the two laſt of this claſs.

The poſterior region preſents the row of dorſal ſpinous proceſſes; the correſponding portions of the muſcular channels of the vertebræ; the tranſverſe proceſſes of the dorſal vertebræ; their articulations with the tubercles of the ribs; a ſeries of ſurfaces belonging to the latter, broader in proportion as they are lower, comprehended between the tubercles and the angles, and giving attachment to the longiſſimus dorſi; and, laſtly, a general line running obliquely from above downwards and within outwards, formed by the ſeries of angles of the ribs. The diſtance between the angles and the tuberoſities increaſing downwards, determines the obliquity of the line juſt mentioned, the increaſing breadth of the ſurfaces which it terminates, and the form of this region, which is of conſiderable breadth below, and becomes narrower as we trace it upwards. This diſpoſition is analogous to that of the anterior region, where the obliquity of the lateral lines produces in the ſame manner an inequality of breadth.

The lateral regions are convex, narrow above, and broader below, formed by the ribs and the intercoſtal intervals. The latter are, in general, diſpoſed like the bones which form them, but with ſome varieties. They are ſhort, and broad above; then diminiſh ſucceſſively in breadth, and increaſe in length down to the junction of the two claſſes of ribs; after which, without growing broader, they again decreaſe in length to the laſt, which is very ſhort: all of them are broader before than behind; hence the diſtance is much greater between the anterior than the poſterior extremities of the firſt and laſt ribs. Theſe ſpaces are all filled by the intercoſtal muſcles.

The internal ſurface of the cheſt, which lodges the principal organs of reſpiration and circulation, alſo offers four regions to our obſervation. The anterior entirely reſembles that of the external ſurface, and is compoſed of the ſame parts. The poſterior has in the middle a prominence formed by the bodies of the dorſal vertebræ, concave from above downwards, and dividing the cheſt into two internal halves. On each ſide of this is a conſiderable elongated concavity, narrow above, broad below, deeper in the middle than in any other part, and containing the poſterior convexity of the lungs. The lateral regions are concave; formed by the internal ſurfaces of the ribs and the intercoſtal ſpaces. The pleura lines them, as well as the poſterior hollows and the pectoral portion, excepting as much of the latter as correſponds to the mediaſtinum.

The ſuperior circumference is ſmall, in compariſon with the inferior, and repreſents an oval placed tranſverſely. It is formed behind by the vertebral column, in front by the ſternum, and on the ſides by the firſt ribs: the clavicles project a little at their inner ends, ſo as to contract this opening in a ſlight degree. The trachea, the œſophagus, the large blood-veſſels, which either go from the heart to the upper parts of the body, or return from the latter to the heart, and ſeveral important nerves paſs through this opening.

The inferior circumference is very large, at leaſt four times greater than the former, and differs from it in being ſuſceptible of enlargement and contraction. The ſuperior, formed by two ribs nearly immoveable, preſerves always the ſame capacity, and is, moreover, protected by a conſiderable thickneſs of parts from the impreſſions of extraneous bodies, that might tend to contract it. To the mobility of the inferior circumference are chiefly owing the variations in the dimenſions of the cheſt, produced by inſpiration and exſpiration, by cauſes which act on it from within outwards, and dilate it, as dropſy, pregnancy, and the various abdominal tumours, or by thoſe which affect it in the contrary way, and tend to contract it, as the ſtays of women. It ſhould be obſerved, at the ſame time, that the viſcera placed at this circumference can accommodate themſelves to theſe varied dimenſions: while thoſe which paſs through the ſuperior aperture, particularly the trachea, would be affected very dangerouſly by any contraction of its ſides. In this inferior circumference there is a large notch in front, of a triangular figure, with the baſis downwards, the ſides of which are formed by the edges of the cartilages of the falſe ribs: in the apex of the triangle the enſiform cartilage projects. On each ſide of this notch there is a convex edge, formed by the cartilages of the falſe ribs. Behind theſe convexities there is a ſmall notch on each ſide, formed by the inclination of the laſt rib, with reſpect to the vertebral column. Several of the abdominal muſcles are attached to all parts of this circumference.

Developement of the Cheſt.—The heart and the thymus, which are ſituated on the median line of the cheſt, in the fœtus, and are of very conſiderable ſize, require a proportional extent in the antero-poſterior diameters, which then predominate, while the tranſverſe are comparatively ſmall, on account of the imperfect condition of the lungs. The ſternum, ſeparated by a wide interval from the ſpine, makes a conſiderable prominence in front, ſo that a large ſpace is left for the heart and thymus. The poſterior foſſæ, at the ſides of the vertebral column, are ſmall, as the ribs are not much curved at this part; hence the prominences behind, formed at the ſides of the ſpine by the curves of the ribs, are not ſenſible at this time. The cheſt is particularly narrow in this direction at the angles of the ribs. The want of this poſterior curvature is the principal cauſe of the augmentation of the antero-poſterior diameters. In fact, the ribs are nearly as long, proportionally, at this time as afterwards; but they ſwell leſs behind and at the ſides, are thrown more forwards, and, conſequently, carry the ſternum in that direction. Theſe curves are formed in the progreſs of age; the poſterior foſſæ of the cheſt are, conſequently, developed, and the ſternum comes nearer to the ſpine. The tranſverſe diameters are now increaſed; but the general capacity of the cheſt is not much augmented in proportion to other parts, as it loſes in one direction what it gains in the other, and its differences in the fœtus, and in the ſubſequent times, are referrible to the different relations of its diameters. Theſe changes affect the ſuperior and inferior circumferences. The former is more capacious from before backwards, but leſs from ſide to ſide: the latter is very wide between the enſiform cartilage and the ſpine; it is one-third wider here than in the adult, in proportion. The tranſverſe diameters are leſs contracted here than in the reſt of the cheſt; ſo that the inferior circumference altogether is remarkable for its great capacity in the fœtus, a diſpoſition which is accommodated to the very marked volume of the gaſtric viſcera, and particularly of the liver, which it includes.

The different bones of the cheſt are not developed in an uniform proportion. The ribs are almoſt entirely oſſified at the time of birth: they are more approximated, particularly below, probably from the great ſize of the liver. The perfection in the oſſification of the ribs may be explained from the nature of the function in which they are employed. Reſpiration commences at the moment of birth, and requires in its organs as great a degree of perfection as is neceſſary at any ſubſequent age: the newly born child reſpires at once as it will reſpire always. The organs of locomotion, on the contrary, go through a kind of education, advance very ſlowly to perfection, and are, conſequently, ſlowly developed.

The ſternum, which is leſs directly concerned in reſpiration, but concurs more immediately in giving ſolidity to the cheſt, is not ſo much advanced as the ribs: on the contrary, it is almoſt entirely cartilaginous.

The contents of the thorax undergo a great change at the time of birth: the lungs, hitherto contracted, are diſtended by the admiſſion of air to a much greater volume than they poſſeſſed before; and that part of the cheſt which contains them muſt be proportionally increaſed.

Towards the period of puberty, although no remarkable change occurs in the ordinary ſeries of phenomena connected with the growth and progreſs of the bones, yet the form of the cheſt ſeems to acquire its fixed character. It either aſſumes that lateral expanſion, and happy conformation which indicate a vigorous conſtitution, or the ſternum projects in front, and gives the alarming preſage of a diſpoſition to phthiſis. At this time the cartilages become more denſe, and the ligaments ſtiffer. The motions of the ribs are more confined. Hitherto they have been the chief agents in reſpiration: but in future the diaphragm is more exerted. The different pieces of the ſternum are joined; the ribs receive more earthy matter, and become more brittle. At a later period the cartilages begin to be converted into bone at their centres, and oſſification goes on until they are made completely bony. The twiſting of the cartilages, which we ſhall mention preſently, is now impoſſible, and the upper part of the cheſt no longer admits of motion in its individual parts. Hence in the old ſubject reſpiration is effected chiefly by the diaphragm.

Mechaniſm of the Cheſt.—This part of the trunk has two principal uſes to fulfil: it protects the included organs by its ſolidity or power of reſiſtance; and it concurs by its mobility in the various functions of theſe organs, particularly of the lungs. We have to conſider it under this double point of view.

The reſiſtance of the cheſt to the action of external force is different on its anterior, poſterior, and lateral aſpects. 1. The thick muſcles placed behind annihilate the effects of falls and blows on that part. Two prominences formed by theſe muſcles, and ſeparated by a groove correſponding to the ſpinous proceſſes, occupy the place of the two longitudinal channels obſerved in the ſkeleton: theſe ſupport the effects of blows. The proviſions for protection in this ſituation, refer to the ſpinal marrow as much as to the pectoral viſcera. 2. In front, where the muſcles are fewer, the mode of reſiſtance varies in inſpiration and exſpiration. When the cheſt is ſtrongly dilated, the ſternum ſupports any effort directed againſt it in the manner of an arch, and more efficaciouſly in proportion as the inſpiration is ſtronger. In this way, individuals lying on their backs ſupport enormous weights on the front of the cheſt: *e. g.* a blackſmith's anvil, on which a horſe-ſhoe has at the ſame time been hammered. Here, however, the mechaniſm is not the ſame as that by which the cranium ſupports a weight bearing on it perpendicularly: in that caſe the bony arch alone is concerned, the muſcles have nothing to do with the phenomenon. In the cheſt, on the contrary, the external muſcles, particularly the ſerratus anticus, draw the ribs ſtrongly outwards, and reſiſt their depreſſion: they are the active ſupports of the bony arch repreſented by the cheſt. If the force be ſuperior to the reſiſtance, fracture enſues: this may either be direct, and affect the ſternum, which is rare; or it may take place by contrecoup at the part which has experienced the greateſt effort, as in the middle of the ribs. Theſe obſervations manifeſtly apply to the true ribs only. Fractures by contrecoup may alſo take place from ſudden blows, where the muſcles have no time to contract and ſupport the ribs, and the latter are conſequently left to the full operation of the force. In exſpiration the cheſt eludes the force by yielding: the ribs are preſſed inwards, and the viſcera are in ſome degree compreſſed. This yielding is much more manifeſt in the lower ribs. 3. The effects of blows, or violence of other kinds, affecting the ſides of the cheſt, are obviated in nearly the ſame manner, whether in inſpiration or exſpiration. The arch repreſented by the rib has its points of ſupport in the ſternum and the vertebral column: the bone may be directly fractured at the point where the violence is offered, which is the moſt common caſe, or by contrecoup, which is more rare. The ſtrength of the ligaments at the anterior and poſterior articulations is ſo conſiderable, and the ſupport afforded by the tranſverſe proceſſes ſo firm, that luxations cannot take place while the joints are in a healthy ſtate. The laſt ribs, which terminate looſely in the abdominal parietes, cannot be ſaid to offer any reſiſtance to the force which is applied to them: they yield towards the abdomen. The firſt and ſecond ribs are ſo covered by external parts, that they can hardly be affected by blows or other kinds of force.

The motions of the cheſt are directed to two principal objects; its dilatation and contraction, which correſpond to inſpiration and exſpiration. It may be dilated in three different directions; perpendicularly, tranſverſely, and from before backwards. 1. The diaphragm alone is the agent of perpendicular dilatation, and produces alone in the adult thoſe ſlight inſpirations, in which but little air enters the cheſt. Its fleſhy ſides, which correſpond to the lungs, deſcend much more than the tendinous centre, which ſupports the heart. (See Diaphragm.) 2. In the next or greater degree of inſpiration the cheſt is firſt dilated perpendicularly, and then tranſverſely by the intercoſtal muſcles. (See Intercostales.) Beſides the cauſes mentioned in that article for the little power of motion in the firſt rib, we may notice the inconſiderable length and great breadth of its cartilage, and its conſolidation with the ſternum, inſtead of being joined by a moveable articulation. The remarkable ſhortneſs and breadth of the rib itſelf alſo concur in producing the ſame effect. In conſequence of the oblique poſition of the ribs, they cannot be elevated without having their middle carried outwards, which produces a tranſverſe enlargement of the cheſt; moreover, this elevation twiſts the cartilages, which throws the ribs ſtill more outwards. 3. In the preceding motion the ribs are carried a little forwards, and as this effect takes place in a greater degree below, where the ribs are longeſt, the ſternum is carried forwards at its lower extremity, the upper remaining nearly motionleſs; and the cheſt is conſequently enlarged from before backwards. This motion, however, is very ſmall in amount, as we may aſcertain by obſerving the reſpiration of a lean individual; it is inſignificant in compariſon to the motion by which the ribs are carried outwards. As the ſternum correſponds to the heart, while the ribs ſurround the lungs, enlargement is leſs needed in the former than the latter direction.

The contraction of the cheſt, correſponding to exſpiration, is effected by a mechaniſm exactly oppoſite to that which we have juſt explained. It takes place from below upwards by the elevation of the diaphragm. In the tranſverſe direction it is effected by the depreſſion of the ribs, which are carried inwards by the twiſted cartilages recovering their original ſtate. The elevation of the bone in inſpiration produces a twiſting of the cartilage; and in exſpiration the recovery of the latter depreſſes the former; ſo that the bone and the cartilage reciprocally determine motion in each other. The effect of this twiſting of the cartilages muſt not, however, be over-rated: in order to make it conſiderable, they ought to be conſolidated to the ſternum, whereas their articulation to that bone allows a certain degree of motion. The greater this motion, the leſs will be the twiſting; and it would not exiſt at all if the articulation were looſe enough to allow full ſcope to the elevation of the rib. It cannot have any effect in the falſe ribs. In proportion as the ribs deſcend and are carried inwards, the ſternum is alſo reſtored, its inferior portion paſſing backwards.

All theſe movements, whether of dilatation or contraction, are much more ſenſible at the lower part of the cheſt, in conſequence of the more extenſive motion enjoyed in this part; a circumſtance that coincides with the greater breadth of the inferior portion of the lungs.

We have to point out, in the next place, the powers by which theſe motions of the cheſt are effected. We may diſtinguiſh two kinds of changes taking place in the cheſt; an enlargement and ſubſequent contraction in the perpendicular direction, and another acting circularly. The diaphragm is the ſole agent of the perpendicular enlargement; and as it extends the cheſt downwards, where the cavity is moſt ample, it produces a very conſiderable dilatation. (See Diaphragm.) This muſcle can deſcend three inches, or more, and has four or five times as much effect in the enlargement of the cheſt, as all the other powers put together. Hence injuries or diſeaſes of it produce the greateſt diſturbance in the function of reſpiration. The perpendicular contraction is effected by the abdominal muſcles; that is, by the obliqui externi and interni abdominis, the tranſverſi and recti. Theſe, which form the ſides and front of the abdominal parietes, yield to the viſcera thruſt downwards by the deſcent of the diaphragm: hence an elevation of the belly is perceptible on inſpiration. They then contract, puſh backwards and upwards the parts which had before deſcended, reſtore the diaphragm to its former ſtate, and conſequently diminiſh the capacity of the cheſt.

The enlargement of the thorax in the circular direction is ordinarily effected by the intercoſtal muſcles, (ſee INTERCOSTALES): and the ſubſequent contraction is owing partly to the reſtoration of the ribs by the elaſtic power of their cartilages, and partly to the action of the triangularis ſterni. But other powers aſſiſt occaſionally, when the circulation and conſequently the breathing are hurried; or when diſeaſe of the cheſt cauſes this function to be performed laboriouſly. Under ſuch circumſtances, every muſcle is brought into action that can aſſiſt in elevating the ſternum or ribs, or in fixing the upper pairs of theſe bones. Hence the ſcaleni, ſterno-cleido-maſtoidei, ſubclavii, cervicales deſcendentes, levatores coſtarum, ſerrati magni, ſerrati poſtici ſuperiores, latiſſimi dorſi, pectorales majores & minores, and trapezii are all employed. The ſhoulders are elevated, the neck is ſtretched, and the head itſelf thrown backwards in the moſt violent efforts of difficult exſpiration. There are alſo auxiliary powers occaſionally employed in exſpiration, but theſe are not ſo numerous as thoſe concerned in inſpiration. The ribs may be depreſſed, not only by the triangularis ſterni, but alſo by the obliqui, recti and tranſverſi abdominis, the quadrati lumborum, longiſſimi dorſi, ſacro-lumbalis, and ſerrati poſtici inferiores.

In the healthy ſubject the enlargement and contraction of the cheſt conſtantly ſucceed each other, and are performed in a regular alternate manner. The diaphragm and abdominal muſcles ſeem to be chiefly employed; but the intercoſtal muſcles alſo aſſiſt. In the female the latter powers are more concerned in reſpiration than in the male.

Although both modes of reſpiration are obſerved to concur in this function in the natural ſtate, it may be and often is carried on by one excluſively. When a rib is broken, or the pleura inflamed, motion of the cheſt is exceedingly painful, and the diaphragm and abdominal muſcles carry on the functions alone. On the contrary, in inflammation of the peritoneum, in the laſt periods of pregnancy, in large dropſical accumulations, the abdominal muſcles and diaphragm cannot act, and the intercoſtals only are then concerned.

In ordinary reſpiration, enlargement and contraction of the cheſt, or inſpiration and exſpiration, are performed in regular alternate ſucceſſion: but this order is often interrupted, and various modifications of the proceſs take place, diſtinguiſhed by particular names.

In *ſtraining*, the diaphragm and abdominal muſcles act together; a deep inſpiration is firſt made, and the diaphragm deſcends conſiderably; the abdominal muſcles then contract, but do not expel air from the cheſt, as they are reſiſted by the former power. The act of ſtraining takes place in all powerful exertions of the body: by it the trunk is fixed, and affords a firm point from which the limbs may be moſt advantageouſly moved. The erectors of the ſpine at the ſame time extend that part, and firmly maintain it in that poſition. Thus all the power of the muſcles moving the limbs is employed in jumping, dragging, puſhing, moving a weight, &c.; and none is loſt in moving the thorax or pelvis towards the limbs, which would be the caſe if thoſe parts of the trunk were not previouſly fixed. So long as the effort laſts, it is obvious that reſpiration muſt be interrupted; hence it is called, in common language, holding the breath: and when it is too long continued, all the inconveniences ariſing from ſuch interruption take place.

The powerful action of the diaphragm and abdominal muſcles ſubjects the contents of the abdomen to preſſure: it impels them and whatever they may contain towards the cavity of the pelvis, and muſt alſo compreſs the blood-veſſels and abſorbents. Hence this effort is employed in expelling the contents of the ſtomach in vomiting, in evacuating the rectum and urinary bladder, and in parturition; it is ſo eſſential in all theſe caſes, that the different objects juſt mentioned could not be accompliſhed without it. Of the amount of the force exerted we may form ſome eſtimate, when we ſee the effects occaſionally produced by ſuch efforts;—the contents of the abdomen are protruded and form ruptures, the viſcera are torn, and the tendons of the abdominal muſcles lacerated.

Whether the paſſage of bile through its ducts, or of calculi through the ſame tubes or the ureters be facilitated by ſtraining, is a doubtful point.

In *panting* there are ſhort and frequent inſpirations, ſucceeded by ſhort and quick exſpirations. It is accompanied with great anxiety, and is attended with, or cauſed by, a more rapid return of blood to the lungs; hence it heats and fatigues. It is produced by violent motion of the body, in wounds of the cheſt, in diſeaſes of the reſpiratory organs, and often in the ſtruggle preceding death.

A long and deep inſpiration, followed by an exſpiration of the ſame kind, conſtitutes *a ſigh*. It ſeems to be an effort at promoting the paſſage of the blood through the lungs; and has been ſaid to be employed when the action of the heart is languid, when it is oppreſſed by the quantity of the blood, or when obſtacles exiſt to its paſſage through the lungs. Sighing takes place under mental affliction or conſiderable bodily fatigue: we generally recover from a ſtate of ſyncope by a ſigh, and aſthmatic perſons frequently ſigh.

In *yawning* there is a ſtill larger inſpiration than in ſighing, performed in a very ſlow and protracted manner, and accompanied by a ſimilar correſponding exſpiration. In both a peculiar ſound is uſually produced. The mouth is opened widely, indeed to the utmoſt extent that the articulation of the lower jaw will allow. Yawning is often ended by a ſigh. That it is produced by bodily fatigue, obſerved moſt frequently on the approach of ſleep and on waking, and takes place alſo when hunger is troubleſome; alſo that newly born children yawn in their firſt attempts at reſpiration, are well known facts; but we cannot explain how this happens. Soemmerring ſays, "that the circulation of the blood through the lungs goes on more ſlowly before yawning; and that we endeavour to obviate by a ſtrong inſpiration, which may promote the circulation through the lungs, the ſenſe of weight, inconvenience, and ſleepineſs that would ariſe from this cauſe." De Corporis humani Fabrica, t. vi. p. 82.

Coughing is an effort of the reſpiratory organs, generally made for the purpoſe of removing from the trachea or its branches ſome irritating matter, as mucus, pus, or any foreign body, through the means of powerful exſpirations, preceded by ſimilar inſpirations. Yet the preſence of a ſtimulus in the ſituation juſt mentioned is not neceſſary, although it is the moſt frequent cauſe: irritation of the diaphragm, as from diſeaſed liver, or an action of the will, can produce coughing. A large quantity of air furniſhed by a conſiderable inſpiration, is violently and ſuddenly expelled, with a conſiderable noiſe, by a very ſtrong and almoſt convulſive exſpiration, and in its paſſage clears away mucus, or any thing elſe which may happen to be in the air paſſages. The air may be driven out at once or at ſeveral exſpirations: in the latter caſe the exſpirations are continued often as long as any air can be expelled, and the emptied cheſt is again ſupplied by an inſpiration accompanied with a peculiar noiſe, as in the hooping cough. Violent and protracted coughing from the interruption of the reſpiratory phenomena, is accompanied with turgeſcence and livid colour of the parts about the head, and with a ſenſe of ſuffocation: when continued for a long time it cauſes head-ache, ſoreneſs of the cheſt, &c.

Sneezing is an action ſimilar in its nature; but more violent in degree than coughing; and it has a different cauſe, *viz.* irritation of the membrane lining the noſe. A ſhort but generally full inſpiration is followed by a moſt vehement exſpiration, ſhaking almoſt the whole body. The expelled air, which in coughing paſſes through the mouth, is directed in ſneezing, through the noſe, for the purpoſe of removing the irritating cauſe. Any extraneous bodies brought into contact with the pituitary membrane, as inſtruments or irritating powders, ſuch as ſnuff, &c. or its own mucous ſecretion, and in ſome individuals ſudden expoſure to ſtrong and dazzling light, will produce ſneezing. Although it is an involuntary effort, it may be in ſome degree increaſed or diminiſhed by the will. It is a ſingular fact, that preſſure about the bridge of the noſe, applied when the inclination is felt, will generally prevent it.

How far the following obſervation of Soemmering tends to elucidate the manner in which ſtimuli applied to the pituitary membrane act on the reſpiratory muſcles, in exciting this convulſive motion of them, is left to the judgment of the reader. "Sneezing ariſes from ſome re-action of the brain, when irritated, through the medium of the naſal nerves, *i. e.* the olfactory and fifth pairs, upon the phrenic nerve; and that it muſt be produced in this way is proved by the fact, that the phrenic and theſe nerves have no connection out of the head." De Corporis humani Fabrica, t. vi. p. 84.

In *laughing*, a full inſpiration is followed by frequent, imperfect, and as it were broken exſpirations, by which the cheſt is not completely emptied. As reſpiration is hurried beyond its natural rate in this act, the circulation is rather quickened; and from the convulſive kind of action in which it conſiſts, a general agitation muſt be imparted to the abdominal contents. In many individuals, a very obvious ſhaking of the cheſt and abdomen accompanies laughter, particularly when violent, ſo as to have become matter of very common obſervation: hence the ſoreneſs experienced from its long continuance. The features are at the ſame time affected in a peculiar manner. In ſome individuals the latter circumſtance is chiefly obſerved. The ſlighter caſes of laughter, which are rather called ſmiling, conſiſt merely of this change of features; but when it goes further, the diaphragm and abdominal muſcles are brought into action. A conſiderable production of ſound takes place at the ſame time, repreſenting in men chiefly the vowels *a* and *o*; in women *e* and *i*. The mouth and its neighbouring parts are principally affected in the face; the corners are drawn upwards and outwards, ſo as in many caſes to expoſe the teeth; the cheek is ſwelled, and the general elevation of the integuments raiſes the lower eye-lid, ſo as to contract the aperture between the two lids. As the interruption in the regular performance of reſpiration produces turgeſcence about the head in violent and long continued laughter, the lacrymal ſecretion is augmented, and a copious flow of tears often enſues.

The cauſes of laughter are partly moral and partly phyſical; with the former we have nothing to do in this article, except to obſerve that laughing and weeping ſeem quite peculiar to the human ſubject. Gentle friction and preſſure of various parts of the body, as the ſoles of the feet, the axillæ, hypochondria, &c. commonly called tickling, are the chief of the latter kind.

Involuntary laughter is a ſymptom of ſome diſeaſes, as hyſteria; and the ancients were of opinion that injuries of the diaphragm produced it: in this caſe they called it riſus ſardonicus. Modern obſervations do not confirm this fact.

Weeping begins with a deep inſpiration, which is followed by ſhort, interrupted exſpirations, at longer intervals from each other than in laughing: theſe often ſhake the thorax and abdomen, and even the head. They are finiſhed at laſt by a ſtrong exſpiration, followed by another inſpiration or a ſigh. This, like laughing, is generally produced by certain mental affections; but in ſome inſtances it owes its origin to phyſical cauſes, as bodily pain; and diſeaſes, as hyſteria, hypochondriaſis, &c. Children generally cry immediately on their birth. The features are conſiderably affected in weeping; the eye-lids are contracted, and the fore-head wrinkled: the mouth has its corners drawn downwards.

Hiccough is ſometimes aſſociated with weeping. It conſiſts of a full, violent, ſonorous, and ſhort, or ſometimes even convulſive involuntary inſpiration through a contracted glottis. Some conſider that the epiglottis is concerned in producing the peculiar ſound of hiccough, and that this organ is ſtruck by the air as it forcibly enters the larynx. The diaphragm appears to be the part principally concerned in this convulſive inſpiration. Sometimes an expulſion of air from the ſtomach through the œſophagus is joined with hiccough. Two, three, or more natural inſpirations and exſpirations take place in the interval between two hiccoughs. It may be occaſionally prevented by depreſſing the diaphragm, and thus holding the breath; or by ſwallowing ſomething ſlowly.

There are many cauſes exciting it. The nearneſs of the ſtomach to the diaphragm occaſions the latter to be often affected by particular ſtates of the former organ. Eating or drinking too much, or unwholeſome articles, is a frequent ſource of the complaint. Wounds or diſeaſes of the ſtomach, or of the diaphragm, may produce it; as alſo various general diſeaſes of the frame, in which it often appears as the precurſor of death.

Inſpiration is immediately concerned in the act of *ſucking*. The lips are cloſely applied round an object, *e. g.* thoſe of the child to the mother's nipple. The air contained in the mouth is then more or leſs completely exhauſted by inſpiration, and the preſſure of the ſurrounding air forces into this more or leſs complete vacuum the contents of the lactiferous tubes. When a liquid is ſucked through a tube into the mouth, the vacuum is formed in that tube, which is embraced by the lips, and the air, preſſing on the ſurface of the liquor, forces it up the tube into the mouth. If the lips are directly immerſed in the fluid, a vacuum is formed, and the fluid riſes into it exactly in the ſame way. The act of *drinking* is effected on the ſame principles.

Deſcription of the Pleura and Mediaſtinum.—The pleura is a thin tranſparent ſerous membrane, lining the cavity of the thorax, and reflected over the contained lungs. Each of the latter organs is encloſed in a particular bag of its own, which bears the ſame relation to the lung, as the pericardium does to the heart; ſurrounding it like a looſe bag or ſheath, and immediately inveſting its ſurface: hence we naturally diſtinguiſh two parts of this membrane, *viz.* the lining of the cheſt (pleura coſtalis), and the external covering of the lung (pleura pulmonalis.)

As there are two lungs, there muſt alſo be two pleuræ, a right and a left. We may form a notion of them by conceiving two membranous bags, forming entire and imperforated cavities, placed laterally with reſpect to each other, and forming, by their appoſition, a partition dividing the cheſt into a right and a left ſide, and containing in its ſubſtance ſeveral of the organs belonging to this cavity. That the two membranous bags are perfectly diſtinct, ſo that nothing can paſs from one to the other, is rendered obvious; 1ſt, by anatomical examinations, in which they may be ſeparated without any injury; 2dly, by experiments on dead bodies, in which fluids may be thrown into one pleura without paſſing into the other; and 3dly, by obſervations on diſeaſed ſubjects, in which water, pus, &c. are often contained for long periods in one pleura only.

In order to underſtand the relations of the pleura to the lungs and to the other thoracic organs, let us deſcribe it as if it began behind the ſternum. From this part it extends outwards, covering the ribs, their cartilages, and the internal intercoſtal muſcles, conſequently lining the ſides of the cheſt. At the heads of the ribs it covers the ganglia of the great ſympathetic nerve, and their branches. When it has reached the back of the cavity, and the vertebral column, inſtead of paſſing in front of that column, it is continued from behind forwards, on the ſide of the aorta and the œſophagus, in front of which it is applied againſt the membrane of the oppoſite ſide, to form the poſterior part of the mediaſtinum. It would be continued in this way from the ſpine to the ſternum through the whole length of the cheſt, if it did not meet with the faſciculus of veſſels entering the root of the lung; it is reflected over theſe, and over the ſurface of the lung, to the ſubſtance of which it is cloſely connected, forming its exterior covering. At the front of the root of the lung it covers the anterior ſurface of theſe veſſels: then is continued from behind forwards on the ſide of the pericardium. It is then applied to the bag of the oppoſite ſide, to form the front of the mediaſtinum, and, laſtly, terminates on the back of the ſternum, where we ſuppoſed it to begin. Below it extends over the whole ſuperior ſurface of the diaphragm.

Thus it appears that the figure of the pleuræ is completely determined by that of the cavity which the membranes line. Each of theſe bags is conical: it riſes into an obtuſe point within the ſpace included by the firſt rib; on the anterior, outer, and poſterior aſpects it is convex, where it lines the ribs and intercoſtal muſcles; below it is concave and expanded over the diaphragm; and on the inſide, where it contributes to the mediaſtinum, nearly plane, but ſlightly concave in the ſituation of the heart. Some anatomiſts diſtinguiſh in the pleura three portions, according to the parts of the cheſt which they cover: *viz.* the coſtal, the diaphragmatic, and the mediaſtinal.

The pleuræ adhere with different degrees of firmneſs to the parts which they line. The medium of this connection is a cellular tiſſue, continuous below with that of the abdominal parietes, above with that of the neck and upper extremities, and in all directions with that which fills the interſtices of the muſcles forming the ſides of the cavity. In the neighbourhood of the vertebræ, and in ſome parts of the mediaſtinum, this tiſſue is copious, and often contains fat: the adheſion is cloſer to the ribs and intercoſtal muſcles, and moſt firm to the diaphragm.

The relative ſituation of the two bags varies at different parts of the cheſt, as different organs are interpoſed between them. Towards the upper and anterior part, immediately under their obtuſe points, behind the arteries coming from the arch of the aorta, and above the pericardium, they are contiguous and ſeparated only by cellular texture. In the middle and lower part of the cheſt, they are widely ſeparated by the intervention of the heart, pericardium, large blood-veſſels, &c. Hence the axis of the cavity muſt paſs from above obliquely downwards and outwards.

The right and left do not preciſely correſpond to each other. The former, on account of the oblique poſition of the heart, lines nearly the whole poſterior ſurface of the ſternum: hence it is broader than the left; but it is at the ſame time ſhorter, becauſe the diaphragm is more ſtrongly arched on this ſide. The left is applied, for the ſpace of ſome inches, to the aorta.

The capacity of the two pleuræ taken together is about one hundred cubic inches in the dead body. It is generally larger in the male than in the female ſex; and is very diſproportionately ſmall before birth. The right exceeds the left in the ſame proportion as the right is larger than the left lung.

The *mediaſtinum* is the partition which ſeparates the two bags of the pleuræ, and divides the cheſt into a right and a left ſide. It is formed by the appoſition of the two membranous ſacs, and extends from the vertebral column to the ſternum and cartilages of the left ribs. We deſcribe in it two lateral ſurfaces, a poſterior and an anterior edge, a baſis and an apex. The lateral ſurfaces are ſmooth, and contiguous to the internal ſurfaces of the lungs, except where the pulmonary veſſels enter thoſe organs: they form the inner portions of the two bags of the pleuræ. The poſterior edge is attached to the ſpine, of which it exactly follows the direction. The anterior is fixed in an oblique line to the ſternum above, and to its edge and the cartilages of the left ribs below. Hence, if we thruſt a pointed inſtrument through the middle of that bone, it will penetrate the right pleura, and not touch the mediaſtinum. The oblique poſition of the heart ſeems to carry with it, as a conſequence, this obliquity of the mediaſtinum. Yet this diſpoſition does not hold univerſally: in ſome ſubjects the mediaſtinum deſcends along the middle of the ſternum: in others, which indeed are very rare, it is inclined from left to right, ſo that the right ſide of the cheſt is narrower than the left. Sometimes the right layer of the mediaſtinum is fixed to the middle of the ſternum, while the left is attached at the articulations of the cartilages. The baſis of the mediaſtinum correſponds to the ſuperior ſurface of the diaphragm, and preſents a wide ſeparation of the pleuræ, lodging the heart and pericardium. The apex correſponds to the upper end of the cheſt; it encloſes the trachea, the œſophagus, and the veſſels and nerves which are entering into or going out of the cheſt.

The mediaſtinum is formed by the two pleuræ, which, inſtead of coming into contact with each other, leave a conſiderable interval between them filled by various organs. Above and in front, they lodge the thymus; below and in front, the heart with its pericardium, and the large veſſels connected to its baſis; behind, the œſophagus and aorta. The two laminæ of the mediaſtinum touch each other only in front of the pericardium, between the lower end of the thymus and the diaphragm, and behind that membrane, in front of the œſophagus, from the firſt dorſal vertebra to the cardiac orifice of the diaphragm. The latter circumſtance has occaſioned a diviſion of the mediaſtinum into an anterior and a poſterior part; the firſt includes all that is placed in front of the œſophagus, the latter all behind it. Theſe diviſions are often called anterior and poſterior, or ſternal and dorſal mediaſtina. The former is the broadeſt and ſhorteſt of the two; it ends about the fifth or ſixth rib; while the latter extends to the eleventh.

In the anterior mediaſtinum, or triangular ſpace placed behind the ſternum and cartilages of the left ribs, beſides ſome fat and cellular ſubſtance, and ſome abſorbing glands, we have the thymus, the trunks of the internal mammary arteries, and the heart. In the poſterior mediaſtinum, or interval of the pleuræ immediately in front of the vertebræ, are found, in addition to ſome adipous and cellular texture, and ſeveral abſorbing glands, the end of the trachea with the commencement of the bronchi, the greateſt part of the œſophagus, with the nerves of the eighth pair, the pulmonary artery and veins, the deſcending aorta, the thoracic duct, and the vena azygos.

When the ſternum is raiſed, in order to expoſe the contents of the thorax, the ſpace ſeparating the two pleuræ behind that bone, and forming the anterior mediaſtinum, is increaſed, becauſe the membranes are partly detached from the ſternum and ribs, to which they before adhered. The cellular ſubſtance occupying the interval becomes filled with air, and is conſequently rendered more ſenſible.

The laminæ compoſing the mediaſtinum are rather thinner than the pleuræ in other ſituations. They are united to each other, and to the parts included between them, by a cellular tiſſue continuous with that of the general external ſurface of theſe bags. This tiſſue, as well as that connecting the different parts together, is tolerably copious, and contains more or leſs fat. It is ſuſceptible of inflammation and ſuppuration, as in other parts of the body; but leſs frequently. Hence abſceſſes ſometimes occur here. The laminæ of the mediaſtinum are, however, more cloſely attached to the ſurface of the pericardium; it is difficult to ſeparate the two membranes completely. The right lamina is more tenſe than the left; a conſiderable protuberance is obſerved in the latter, and formed by the ſituation of the heart: hence the former only, if either, can have any effect in ſupporting the diaphragm.

The mediaſtinum receives its peculiar blood-veſſels. In front its arteries come from the internal mammary, and the comes nervi phrenici; behind, from the inferior thyroid, the ſuperior intercoſtal, the pericardiac, œſophageal, and bronchial arteries. The veins correſpond to, and accompany theſe.

The mediaſtinum divides the cheſt into two lateral halves; ſeparates the membranous bags containing the lungs, and renders their action independent of each other. It confines alſo to one ſide various morbid affections, as effuſions of blood, pus, &c. Some phyſiologiſts conceive that it is further uſeful, by ſupporting the weight of the oppoſite lung, when we lie on the one ſide, and protecting therefore the lung of the ſame ſide on which we lie.

The pleura is nearly tranſparent, ſo that we can eaſily diſtinguiſh through it the colours of the ſubjacent parts. The fibres of the diaphragm and intercoſtal muſcles, the intercoſtal veſſels and the ribs are immediately diſcerned through this membrane. We can ſtill more clearly perceive all the ſhades of colour in the lung through the pleura pulmonalis; this indeed is thinner than the pleura coſtalis, and adheres very cloſely to the organ. Boiling deſtroys this tranſparency, and gives the membrane a dirtyiſh white appearance. It is very ſtrong in proportion to its thickneſs. Concerning its intimate organization we have nothing farther to ſay than what the reader will find in the general account of the ſerous membranes.

The arteries and veins of the pleuræ, beſides what have been already mentioned as belonging to the mediaſtinum, are derived chiefly from the intercoſtal veſſels. The abſorbents are exceedingly numerous, and paſs through glands ſituated about the heads of the ribs to the thoracic duct.

The internal ſurface of the pleura is in all parts ſmooth, pale, and covered by a ſerous moiſture produced from the exhaling veſſels of the membrane. This obſervation applies as well to the pleura pulmonalis, as to the p. coſtalis: the internal ſurface of the former conſtitutes the outer ſurface of the lung: the two portions of the membrane are contiguous at all points. In a living animal, or in one recently ſlaughtered, and opened whilſt yet warm, this ſerous exhalation eſcapes in the form of a light whitiſh ſmoke: the ſurface of the membrane has a ſoft ſlippery feel, but no actual fluid is diſcerned in the cheſt. When the body has cooled, this vapour is condenſed into a few drops of liquor, which is ſoon increaſed by the tranſudation through the blood-veſſels, and then it conſtitutes what authors have deſcribed under the name of liquor pleuræ. It has been queſtioned whether this, or the fluid of the pericardium, which is alſo in very ſmall quantity, compoſed the watery part of what iſſued from the ſide of our Saviour when pierced by the ſoldier. We are of opinion, that the period, at which this occurred after death, was too recent for us to ſuppoſe that any fluid, or if any, not more than an exceedingly minute portion of fluid, could be contained in the pleura or pericardium. Conſequently the fact does not admit of a natural explanation, but muſt be referred to the miraculous powers ſo ſignally exerted in other reſpects on this occaſion.

This ſerous exhalation is conſtantly abſorbed and renewed. It keeps the lung in an inſulated ſtate, and ſeparates it from the parietes of the thorax. How far this is eſſential to the functions of the organ, will be examined preſently.

The exhalation of the pleura is variouſly changed in diſeaſe. It conſiſts of actual fluid, either depoſited in unuſual abundance, or not abſorbed with the uſual activity, in hydro-thorax. In pleuritis it is the coagulating part of the blood, which afterwards forms the adheſions of the two pleuræ, ſo commonly ſeen in the dead body, that hardly any ſubject is entirely free from them.

As the pleura pulmonalis and coſtalis are always contiguous, it follows that the lung always fills the cavity of this membranous bag. If we diſſect away carefully the muſcular parts, that fill the interval of two ribs, ſo as to expoſe, without penetrating the pleura, the tranſparency of the latter membrane allows us to ſee the lung through it, and to ſee that there is no interval between them, but that they are in accurate contact in all parts of the cheſt. The reſult of this examination is the ſame, both in the living and the dead ſubject. From this repreſentation it follows that the motions of the cheſt muſt be accompanied by correſponding changes of the lungs; that air will enter into or paſs out of thoſe organs through the trachea, which is conſtantly open, according as the cheſt is enlarged or diminiſhed; and, in fact, that the dilatation and contraction of the thorax are conſtantly attended with a ſimilar dilatation and contraction of the lungs. Theſe motions of the cheſt refer entirely to the functions of the lungs, which are paſſive in reſpiration, which poſſeſs in themſelves no independent power of enlargement and diminution.

Different opinions were, for a long time, entertained on this ſubject; it was ſuppoſed that a ſpace filled with air, ſeparated the lungs from the containing cavity. A frequent and careful performance of the diſſection mentioned above, has however ſhewn the lung always in contact with the pleura, when the latter has not been injured; and the cheſt has been opened under water without a ſingle particle of air eſcaping. Indeed it is only by this contact that the function of reſpiration can be explained, if we admit the paſſive nature of the lung: the expanſion and contraction of the cheſt would be no longer attended with enlargement and diminution of the lung, if air were contained between this viſcus and the ſides of its containing cavity.

All the preceding obſervations apply to the natural ſtate of the parts, in which the bag of the pleura is entire; if that be wounded, ſo as to make a communication between its cavity and the external air, the lung no longer continues in contact with the ſides of the cheſt. It has been almoſt univerſally received, that when an opening is made into the thorax in the living ſubject, the lung falls from the ſides of the cavity, becomes diminiſhed in ſize, or, in technical language, *collapſes*, and remains motionleſs. Such is the repreſentation given by Haller (Element. Phyſiol. lib. viii. ſect. 2. § 6.) If an extenſive wound be made on both ſides, it ſeems generally admitted that the lungs are rendered motionleſs, that reſpiration ſtops, and the animal dies. But it is not equally clear that a ſmall wound is attended invariably with collapſe and a fatal termination. Caſes are recorded, in which penetrating wounds of the cheſt have been attended with protruſion of the lung—a ſtate apparently the direct reverſe of collapſe. And Mr. Norris, who had met with ſuch an inſtance, opened the thorax in ſheep, on one and both ſides, ſufficiently to enable him to introduce a finger. Reſpiration was not rendered difficult. (See Memoirs of the Med. Soc. of London, vol. iii.) Thus it ſhould ſeem that the ſize of the wound influences the reſult of the experiment in a living animal; which is not irreconcileable to the repreſentation we have already given of the paſſive ſtate of the lung. For the ſurface expoſed to the external preſſure of the atmoſphere by a ſmall wound may not counteract the effect produced by the contact of the two pleuræ in the whole of the reſt of their extent. In all theſe experiments the wound ſhould be carefully kept open, if we are to derive any inſtructive inferences from the reſult: if its ſides are allowed to come in contact, no collapſe of the lung could be expected. We do not know how to explain the protruſion of the lung from wounds.

If a wound be made in the lung, when there is no communication between the thorax and the external air, as by a broken rib, air eſcapes into the thorax, and cannot paſs out: a collapſe of the lung is a neceſſary conſequence. This is what occurs in emphyſema, and occaſions the difficulty in breathing; the air alſo eſcapes through the wound of the pleura into the cellular ſubſtance of the body.

When a wound is made into the cheſt, in the dead ſubject, the lung, which was before in contact with the pleura, immediately recedes from it. The ſeparation is more marked in front, leſs at the ſides; and at laſt the lung, much diminiſhed in volume, lies againſt the back of the cheſt. Of courſe an empty ſpace is left, proportioned to the collapſe of the lung, and the pleura is ſtretched over this, with a whitiſh opaque appearance. This experiment never fails, except when the lung is adherent. The air contained in the cheſt at the time of death is cooled as the reſt of the body grows cold; its volume muſt be diminiſhed, and the lung containing it muſt undergo a correſponding diminution, by virtue of its contractility of tiſſue. Hence a tendency to the formation of a vacuum enſues, in conſequence of which the preſſure of the external air puſhes the diaphragm ſtrongly upwards, and makes it very concave towards the abdomen. This is the condition in which that muſcle is conſtantly found in the dead ſubject, although we might ſuppoſe that the weight of the thoracic contents, preſſing on it above perpendicularly, would drive it downwards when it is no longer ſupported by the abdominal viſcera below. If a ſmall opening be made in it penetrating the cheſt, it immediately ſinks, and a ſpace is created above it by the atmoſpheric air entering the cavity.

How is the collapſe of the lung in the dead ſubject to be explained? Are we to conceive that air eſcapes through the glottis when the lung ſinks in conſequence of an opening in the cheſt? On this ſuppoſition the organ muſt previouſly have been maintained by its contact with the ſides of the cavity, in a ſtate of greater diſtention than it would exhibit if left to itſelf. The acceſs of the air to the thorax enables the lung to paſs into its natural ſtate, by allowing its contractility of tiſſue full ſcope for exertion. But we have aſcertained that the phenomenon, called collapſe of the lungs, takes place in the dead body, when a ligature is placed on the trachea, ſo that the contractility of tiſſue cannot operate. It depends entirely on the ſinking of the diaphragm, which gives way towards the abdomen, and is followed by the lung. The latter organ therefore is not diminiſhed in ſize, and cannot with any propriety be ſaid to have ſuffered collapſe. Let it be remembered that the concavity of the diaphragm is maintained by the preſſure of the atmoſphere, forcing it into the cheſt, to fill the ſpace left by the gradual diminution of volume of the lung conſequent on the cooling of the air, and its contractility of tiſſue; and that this ariſes entirely from the accurate mutual contact of the lung and thoracic cavity. When the latter is expoſed, the air preſſes on the lung at the ſituation of this expoſure above, as much as it does againſt the diaphragm below, and theſe two organs conſequently take that poſition which their weight and connections, independently of any other cauſes, would determine. We believe that the contractility of tiſſue of the lung has been exerted nearly to its full extent, before the cheſt is opened, and that it would be exerted to the utmoſt extent, if the diaphragm could be forced up ſufficiently to fill all the ſpace left by the contraction of the organ. It ſeems to us that the lung does contract after the cheſt has been opened, and conſequently that the diaphragm is not capable of filling all the ſpace which the contractility of the lung might leave. Bichat refers the collapſe of the lung in the dead ſubject entirely to the cooling of the air contained in this organ after death. This, he ſays, produces a vacuum between the lung and the pleura coſtalis; the lung collapſes before the cheſt is opened, becauſe the air-cells contract in proportion as the air is condenſed. The aſſertion that a vacuum exiſts is contrary to all obſervation; indeed the thing is obviouſly impoſſible. If we underſtand him rightly, he denies that the collapſe takes place on opening the cheſt. "Thus," ſays he, "there is this difference between opening a dead and a living body: in the former the lung has already collapſed; in the latter it collapſes at the inſtant of the opening. The contraction of the cells, when the cooled air is condenſed and occupies leſs ſpace, is an effect of the contractility of tiſſue, which remains in the organs to a certain degree after death. Moreover, if the lung collapſed in the dead body at the moment of opening the cheſt, the cauſe would be in the preſſure of the external air, which would expel through the trachea what was contained in the organ. But if, in order to prevent the exit of the air, you cloſe the trachea, and then open the cheſt, the lung is found in the ſame ſtate of collapſe; therefore the air had quitted it already. Make the ſame experiment on a living animal, and you will always prevent the collapſe of the lung." Recherches ſur la Vie et la Mort, p. 193, note 1.

It remains for us to advert again to the ſerous ſecretion which moiſtens the ſurface of the pleura. Is this ſecretion neceſſary to the phenomena of reſpiration? is that function ſenſibly impeded, when the ſerous fluid is no longer produced, and the pleura pulmonalis and coſtalis are united together throughout? For a long time the affirmative of this queſtion has been maintained, and it has even been uſual to attribute habitual difficulty of breathing to adheſions between the lungs and pleuræ. Yet the following conſiderations render this ſuppoſition very doubtful. 1. It has been clearly proved, that in the healthy ſtate the lungs and the containing cavities are perfectly contiguous, both in inſpiration and exſpiration: reaſoning alone might have ſhewn this. What end do the movements of the cheſt ſerve, if the lungs poſſeſs in themſelves an independent power of motion?

Since, then, the lungs and cheſt always move together, how can there be an empty ſpace between them? and if there can be none, how can an accidental union obſtruct the motions? 2. Adheſions between the pleura pulmonalis and coſtalis are extremely frequent. They are found, not only in individuals who have died after a long diſeaſe, but alſo in thoſe whom a violent death has ſurpriſed in a ſtate of health. In many inſtances the whole ſurface of the lung adheres to its cavity: yet in general the individuals have enjoyed perfect freedom of reſpiration. We muſt therefore conclude, that a continuity of ſurface between the lungs and cheſt does not injure the freedom of the reſpiratory functions. The utility of the ſerous fluid does not then appear ſo clear to us in the pleura, as in other cavities of the body. In the reſpiratory apparatus, the motions of the ſides of the cavity and of the contained organs hold a certain neceſſary and invariable relation to each other. The brain tends to move in an immoveable bony caſe; the gaſtric viſcera may change their poſition and relations to each other, without any alteration in the abdominal parietes: in the ſynovial cavities there are two ſurfaces conſtantly moving in an inverſe direction to each other, &c. We every where ſee the different portions of a ſerous ſurface ſliding on each other in a more or leſs marked degree, and we naturally conclude that the preſence of a fluid is indiſpenſible to that motion. The thorax alone preſents to us two ſerous ſurfaces always in contact at the ſame points.

The *two lungs* occupy the ſerous cavities on the ſides of the cheſt, lined, as already deſcribed, by the pleuræ. They are ſeparated from each other by the mediaſtinum, but united by the circumſtance of their receiving from two common trunks (the trachea and pulmonary artery) the air and blood which are neceſſary to their phenomena. They are not ſymmetrical, but differ both in ſize and form, exhibiting the irregularity which belongs to the organs of the organic life; or rather holding a middle place in this reſpect, as well as in their functions, between thoſe and the organs of the animal life. The heart, which is turned to the left, and placed almoſt entirely on the left ſide of the cheſt, diminiſhes the tranſverſe diameter of the correſponding pleura: the liver elevates the diaphragm very ſenſibly on the oppoſite ſide, ſo as to reduce the perpendicular meaſurement of the right pleura. Hence the left lung is the longeſt, and the right the broadeſt of the two.

Their volume, in the natural ſtate, is always exactly the ſame as the capacity of the bags of the pleuræ: their external ſurface is conſtantly in contact with theſe cavities. As they have no power of motion in themſelves, and follow every change which the ſides of the cheſt undergo, their capacity is conſtantly varying: when the cheſt is enlarged, they are dilated by the entrance of air into their ſubſtance through the trachea, and when it is contracted, they undergo a correſponding diminution by the expulſion of air. For further explanation and proofs on this ſubject, ſee the account of the pleura. Yet we cannot always judge of the volume of the lungs by the apparent extent of the pectoral cavity: the heart differs conſiderably in ſize, and ſimilar variations of the liver, influencing the height to which the diaphragm aſcends, are ſtill more common. The collapſe of the lungs, which we have conſidered in ſpeaking of the pleura, is leſs marked when theſe organs are diſtended with blood: it is generally leſs in children than in adults, and does not take place at all in the converſion of theſe organs into a ſolid maſs like the liver, at leaſt in the parts immediately affected. Thus the bulk of the lungs depends more on the fluids which they contain, particularly the blood and air, than on their ſolid ſubſtance. They are dilated in inſpiration; but ſtill thoroughly penetrated with air in the moſt complete exſpiration. Long and continued compreſſion or extraction of the air by an exhauſting ſyringe reduces them to ſo ſmall a bulk, that they do not equal one-fourth of the cavity which is deſigned to contain them. Preternatural accumulations of fluid, as water or pus, diminiſh the ſize of the organs in the ſame way during life. The moſt numerous inciſions and the ſtrongeſt preſſure will hardly get rid of all the air from the lungs: if we cut a very ſmall portion, and ſqueeze it moſt forcibly, there is ſtill enough air to keep up the ſize beyond what the ſolid matter would cauſe, and it ſtill ſwims in water. In ſhort, this air can be completely got rid of only by ebullition, maceration, or means that entirely deſtroy the texture of the organ.

The lungs generally contain more blood after death than during life, as an accumulation takes place in their veſſels in the act of dying: the quantity of this fluid influences the bulk of the organ, when the cavity of the cheſt is expoſed. When there is much blood, inciſions into the lung produce a leſs marked diminution of volume than we might expect: they only give iſſue to the air and not to the blood. The ready eſcape of the air, too, requires a free communication of the air-cells with each other, which the ſtagnation of the blood prevents, by confining the air in every part, ſo that only the cut portion is evacuated by the inciſions. Where the individual has died of hemorrhage, the lungs are almoſt entirely free from blood, and owe their volume to the air: here ſuperficial inciſions produce a ſudden and marked collapſe. This has been particularly obſerved in perſons executed by the guillotine: three or four inciſions have ſpeedily reduced the lung to nearly the half of its original ſize. (Bichat, Anat. Deſcript. t. iv. p. 12.) For the ſame reaſon, the degree of collapſe of the lung will be much influenced by the quantity of mucous fluids contained in the air-veſſels and cells of the lungs.

The lungs are the lighteſt organs in the body; they conſtantly ſwim when immerſed either entire, or in parts, in water. This property depends obviouſly on the ſame cauſe as their volume, namely, the air which they contain. When entirely deprived of this fluid, and reduced to their own ſubſtance, they do not ſwim. This is ſeen when one of them is ſo compreſſed and flattened by the effuſion into the cheſt of a large quantity of fluid, as to ſerve no longer for the purpoſes of reſpiration. In certain diſeaſes, too, the lung is rendered ſolid and impervious to air, and then ſinks in water; but this is a pathological phenomenon. Immerſion in water is, therefore, the ordinary and beſt method of determining the ſpecific gravity of the lung. The greater or ſmaller quantity of blood which may be contained in their veſſels at the time of health occaſions them to vary in weight when compared in different ſubjects.

There can be no doubt that the lungs of a perſon, who has died of aſphyxia, are heavier than thoſe of one who has periſhed from hemorrhage: and that theſe organs will be lighter after a chronic diſeaſe, which has exhauſted the vital powers, and diminiſhed the energy of the circulation, than after ſtrangulation, in which there is a conſiderable afflux of blood into them to the laſt moment.

The form of theſe viſcera is in general conical, with the baſis downwards, and the apex upwards. This form is tolerably conſtant, becauſe it depends on that of the thorax, which varies little in its natural ſtate. They correſpond immediately to the ſolid ſides of the cheſt only at the upper and outer parts: on the inner ſide they lie againſt the heart, and below are ſeparated from the abdominal organs by the diaphragm: in the two latter aſpects, therefore, their form is influenced by that of the neighbouring parts. The heart, placed chiefly on the left ſide of the cheſt, leaves a much narrower ſpace for the baſis of the left than for that of the right lung. The natural or accidental varieties in the form of the cheſt, as curvatures of the ſpine, with the concomitant deviations in the figure and direction of the ribs, are always attended with correſponding varieties in the lungs. We may deſcribe in each lung, beſides the baſis and apex, two ſurfaces, an internal and external.

The external ſurface is convex in its whole extent, and correſponds to the thoracic parietes, from which it is ſeparated by the pleura coſtalis; it is ſmooth and poliſhed, and lubricated by a ſerous exhalation. A conſiderable groove is obſerved in it, beginning behind a little below the apex, and running obliquely forwards and downwards to the baſis. This groove runs throughout the ſubſtance of the lung, which it divides into two nearly equal halves called lobes: theſe are connected together at the root of the organ by the reflexion of the pleura, and by receiving their blood-veſſels from a common trunk. The two lobes are in contact with each other by broad and flat ſurfaces, which are ſmooth and lubricated, like the external ſurface of the lung, as they are covered throughout by the pleura. The upper lobe of the right lung is marked by another groove, directed obliquely from above downwards, and within outwards; ſo that its maſs is divided into three lobes: the middle is the ſmalleſt, and triangular in its figure. This ſecondary groove is more variable than the former in its exiſtence, its length and depth. Sometimes, but very rarely, it is not found; and it is often incomplete, ſo as not to divide the middle lobe entirely from the ſuperior. It is very ſeldom ſeen in the left lung.

The internal ſurface is nearly plane, and divided into two unequal portions by the inſertion of the bronchi and pulmonary veſſels, which takes place towards its upper and back part.

It is at this point, which is called the root of the lung, that the pleura is reflected over the organ: here, therefore, the pleura pulmonalis and coſtalis are continuous. This is the only ſituation in which the lung adheres to the containing cavity; the ſurface is free and unattached every where elſe: it is ſometimes called, from this circumſtance, the ligamentum pulmonis.

The bronchus, the pulmonary artery and veins, the nerves and lymphatics of the organ, ſurrounded and connected by cellular ſubſtance, and forming a ſingle large faſciculus, paſs out of the mediaſtinum to the lung. The pleura is reflected over this faſciculus, covers it, and is continued over the lung. That portion of the inner ſide of the lung which is behind the root is narrow, and correſponds to the lateral ſurface of the vertebral column: the anterior diviſion is broader, and is contiguous to the heart and pericardium; it is ſlightly concave at this part. Above and below the inſertion of the veſſels the inner ſurface of the lung is not divided into theſe two parts.

The external and internal ſurfaces of the lung are united by two edges. The anterior is thin, particularly below, irregular in its outline, directed obliquely downwards and forwards, and has in the left lung a ſmall notch correſponding to the apex of the heart. The poſterior is obtuſe, not clearly marked, directed vertically, and correſponding to the hollow at the angles of the ribs. On the latter is ſeen, above, the commencement of the great groove, which divides the lung into two lobes.

The baſis of the lung reſts on the diaphragm, and is concave, to ſuit the convexity of that great muſcular partition. It is directed obliquely from within outwards, from above downwards, and from before backwards; correſponding in this reſpect entirely to the diaphragm. The concavity of the baſis is more marked in the right than in the left lung, on account of the greater convexity of this ſide of the diaphragm produced by the liver. The termination of the great groove is found on this ſurface of the organ, ſo that the two lobes are diſtinct here as well as in other ſituations: but the ſuperior lobe contributes to the formation of the baſis only in a very ſmall part of its extent, particularly on the right ſide. The circumference of the baſis preſents a thin edge, with a rather irregular outline interpoſed between the ribs and the diaphragm, near the attachment of the latter. This is more ſenſible on the right than on the left ſide.

Its appearance varies according to the different ſtates of the lungs; the preceding deſcription applies to the dead ſubject. In inſpiration, the diaphragm deſcends and becomes nearly plane; the lung follows it, and aſſumes a correſponding figure, its edge, inſtead of being thin, becoming thick, and no longer included between the diaphragm and ribs.

The apex of the lung is ſmall and obtuſe, and correſponds to the cul-de-ſac of the pleura under the firſt rib. In this way it is completely inſulated from the lower part of the neck. It exhibits ſeveral more or leſs marked tubercular riſings.

The whole ſurface of the lungs is unconnected to the cavity, except in the ſituation of the ligamenta pulmonum. The oppoſed ſurfaces of the lobes are in the ſame way unconnected to each other, and covered by the ſerous membrane. All theſe parts are moiſtened by a ſerous exhalation.

The colour of the lungs, when not influenced by that of the fluids which they contain, is extremely pale; ſometimes a ſlight tawny brown, but more frequently grey or aſh-coloured; and ſometimes completely white. This colour is ſeen over the whole organ, both on its ſurface, and in the interior, when it is quite free from blood; but is no longer viſible when the lung is loaded with that fluid. Hence we underſtand why we meet with it ſo ſeldom in the dead body, ſince a diſtention of the pulmonary veſſels with blood is one of the moſt ordinary phenomena of death. The only caſes in which we can expect with ſome certainty to find the lungs exhibiting this pale colour throughout, are thoſe of deaths from hemorrhage. It was noticed by the French in individuals who periſhed by the guillotine. We may often obſerve it in ſome particular points of the organ, where the abſence of blood may be aſcertained by inciſions. The tawny or greyiſh colour of the lungs is interrupted by ſmall black or brown ſpots, irregularly diſſeminated over the ſurface, and very variable in number and form. Often the organ is very thickly ſpotted in this way; at other times they are ſcattered here and there at conſiderable diſtances; ſometimes, but very ſeldom, they do not exiſt at all. Theſe ſpots do not depend in the leaſt on the blood. Simple inſpection is ſufficient to prove that they belong to the organization of the part. They are very diſtinct in the paleſt and moſt bloodleſs lungs, and may be eaſily recogniſed in the general livid tint of thoſe which are moſt loaded; they ſeem to poſſeſs always the ſame intenſity of colour; and they are always circumſcribed, while the marks ariſing from the blood end imperceptibly. Theſe black ſpots preſent every variety of figure. Some are ſuperficial, others extend into the ſubſtance of the lung, and ſome are found in the interior of the organ. They ſeem to belong entirely to the pulmonary tiſſue, as they are never ſeen on the bag of the pleura, and are found in the ſubſtance of the lung.

But generally the lungs are loaded with blood at the time of death, and do not conſequently exhibit the paleneſs which we have deſcribed as belonging to their proper tiſſue. They are uſually livid, violet-coloured, browniſh, or reddiſh; and the mixture of theſe various tints gives them the marbled appearance, which has generally been regarded in diſſecting rooms as the natural ſtate of the organs, although it is merely produced by death. The brown, blueiſh, or violet colour is the moſt frequently obſerved, and occupies the lung moſt extenſively. It depends on the preſence of venous blood, which ſtagnates as ſoon as reſpiration has ceaſed to colour what the right ventricle ſtill impels. The tint varies as the blood is accumulated more or leſs in particular ſituations. The higheſt degree of this congeſtion produces the black obſerved in the lungs of thoſe who die of aſphyxia; the brown or violet colour is cauſed by a ſlighter degree of the ſame effect. The colour is always the deepeſt in the moſt depending part of the lung, as the blood, obeying only the laws of gravity after death, ſettles in the loweſt parts. From the ordinary poſition of the body this deep colour is uſually ſeen at the back of the lung; but if the ſubject be laid on the face, the ſame phenomenon is exhibited in front. Theſe dark colours are not the only ones obſerved in the lungs; more or leſs extenſive patches of a bright red are often ſeen; this may occupy a large portion of the organ, while the reſt is brown or violet-coloured. This red colour is univerſal in the lungs of children, which do not preſent the black ſpots; the former gradually diſappears, and the latter increaſe with the progreſs of age. The ſame bright tint extends into the ſubſtance of the lung. We are at a loſs for a ſatisfactory explanation of this appearance: if it aroſe from the blood being acted upon after death, by the air contained in the pulmonary air-cells, we ſhould expect to find it more univerſal and more frequent. The parts of the lung, however, in which this tint is obſerved, certainly contain ſcarlet blood, and owe the colour to that.

The lungs are the leaſt denſe, and leaſt reſiſting of all organs formed of ſolid tiſſues. They yield readily to compreſſion, preſerve the mark of the preſſure, and are reſtored imperfectly to their original ſtate. This obſervation applies only where they are not loaded with blood, but contain merely that quantity of air, which never leaves them after they have been once diſtended with it. When full of blood, they acquire a conſiſtence foreign to their own ſubſtance, reſiſt preſſure more effectually, and reſtore themſelves more readily. Hence ſoftneſs and flaccidity more particularly characterize the lungs of perſons who have died of hemorrhage. When we ſqueeze the air forcibly into a part of the lung, a peculiar crackling noiſe is produced by the burſting of the air-cells: this crepitation does not take place in diſeaſed lungs.

The ſoftneſs of the pulmonary texture ariſes from the lungs being entirely compoſed, as we ſhall ſee preſently, of various vaſcular ſyſtems. It accords very perfectly with the paſſive part that they perform in the reſpiratory phenomena: poſſeſſing no power of motion in themſelves, they expand and contract merely in conſequence of motions of the cheſt.

The lungs are compoſed of a cartilaginous and membranous tube, by which air is conveyed into them; of the pulmonary artery and veins, of which the former terminates the ſyſtem of black blood, and the latter commence that of red blood; of the bronchial veſſels concerned in the nutrition of theſe organs; of a peculiar tiſſue, compoſing a congeries of minute cells, which receive the air admitted in reſpiration; and of lymphatics and nerves. Theſe parts are all united by cellular tiſſue, and covered externally by the reflected pleura.

The air-veſſels compoſe the eſſential part of the lungs, with reſpect to their functions as organs of reſpiration. They introduce the fluid by which the blood is changed; this proceſs goes on at their ſurface; and the air, after ſerving the purpoſes of reſpiration, is expelled through them. When taken altogether they form the cavity of the reſpiratory apparatus, which is analogous to that of the digeſtive canal, in having a mucous lining, but differs in its arrangement, as it is ſubdivided into a vaſt number of canals, decreaſing ſucceſſively like arteries. Theſe are the only tubes in the body conſtantly open; it is neceſſary that the air ſhould have free and conſtant acceſs to them. This order of tubes is begun by a ſingle trunk, which unites the two lungs, and neceſſarily renders their phenomena ſimultaneous. The common trunk is called trachea (aſpera arteria, trachée artère); and its primary diviſions the right and left bronchi.

The *trachea* is placed in front of the vertebral column, extends from the upper part and middle of the neck to the upper part of the cheſt, beginning immediately below the larynx, and ending about the level of the ſecond or third dorſal vertebra. It is placed on the middle line of the body, and is ſymmetrical in its whole extent; in this reſpect it approaches to the external organs: the ſymmetry ceaſes in its diviſions. It appears cylindrical in front, but is flattened behind. Its diameter varies according to the age of the ſubject, and the natural volume of the lungs; it may be about eight or ten lines in the adult, and is exactly the ſame with that of the larynx, meaſured at the cricoid cartilage. It continues the ſame through the whole length of the trachea.

In front it is covered above by the two portions of the thyroid gland, which unite together at the middle of the tube. Lower down the ſterno-hyoidei and ſterno-thyroidei, and the inferior thyroid veins cover it. In the cheſt it is encloſed in the poſterior mediaſtinum, and correſponds to the thymus, to the left ſubclavian vein, the arteria innominata, and the arch of the aorta. Behind it covers the œſophagus, and towards the right the vertebral column. On the ſides it is covered above by the lateral portions of the thyroid gland, and is contiguous below to the common carotids. A looſe and abundant cellular tiſſue forms the medium of its connection to all theſe parts. The ſuperior extremity is connected to the cricoid cartilage by a ligamentous ſubſtance; the inferior is placed at the right ſide of the deſcending aorta, is bifurcated, and produces the two bronchi. The latter begin about the ſecond or third dorſal vertebra, and ſeparate from the common trunk nearly at a right angle, yet they go with ſome obliquity, downwards and outwards, each to its correſponding lung. Here we begin to meet with the irregularity of form that characterizes the organs of the internal life. The left bronchus is ſmaller than the right, and takes a much longer courſe: it paſſes under the arch of the aorta, while the other goes immediately to its lung. Theſe tubes enter the lungs at the ſituations already deſcribed as the roots of thoſe organs. They ramify in every direction, and divide into branches, becoming ſucceſſively ſmaller and ſmaller. Theſe ſubdiviſions are ſo numerous, that every part of the lung contains them. The exact manner of their termination is not underſtood.

The air-tubes are compoſed of three parts, an exterior membrane, of a fibrous and probably muſcular texture; a cartilaginous ſtructure, which is united to the preceding; and a mucous lining. The exterior membrane riſes above from the circumference of the cricoid cartilage, and occupies the whole extent of the trachea and bronchi, forming a very eſſential part of thoſe tubes. It is tolerably thick in the greateſt part of its courſe, but grows thinner in the ſmaller ramifications of the bronchi, where it cannot be eaſily traced. It is formed of parallel and cloſely arranged longitudinal fibres, the nature of which is doubtful; ſome conſider them as muſcular, others regard them as a fibrous organ, to which their appearance is very ſimilar. This membrane alone conſtitutes the ſolid portion of the trachea behind; and hence ariſes the flattened figure of the tube at that part. This peculiarity in the back of the trachea has been referred to the ſituation and motions of the œſophagus, which lies cloſe behind it: but the ſame ſtructure exiſts in the bronchi alſo, where it cannot admit of that explanation. The arrangement is different on the anterior part and ſides of the trachea, in two-thirds at leaſt of the circumference of the tube. The fibrous membrane is interrupted by portions of cartilage (annuli cartilaginei), which keep it on the ſtretch, and thereby preſerve the air-tubes conſtantly open. Each of theſe cartilages repreſents two-thirds of a circle. They are bent on themſelves, flattened on their ſurfaces, uniform in length, but of different breadths. Their convexity forms a part of the exterior ſurface of the tube; their concavity correſponds to the mucous membranes, from which a thin cellular ſtratum ſeparates them. Their ſuperior and inferior margins are rounded, continuous on the outſide with the fibrous tiſſue, and ſlightly prominent through the mucous membrane on the inſide. Their extremities project more or leſs behind in the fibrous tiſſue, are all on the ſame level, are rounded, and a little bent upwards. They vary in number from about ſixteen to twenty; they may be more or leſs broad; and, as the length of the tube is nearly uniform, they muſt be more numerous in proportion as they are narrower. In general, they are broader in front, and diminiſh progreſſively to the back part: but the reverſe of this ſometimes happens; or two may be united at their edges. Commonly their direction is horizontal to the axis of the trachea; but many of them are often more or leſs oblique.

In colour and texture they reſemble the fibro-cartilages of the organs of ſenſe: they are very elaſtic.

The firſt cartilage is generally much larger than the ſucceeding ones; the laſt has a prolongation from its middle correſponding to the bifurcation of the bronchi.

In the ramifications of the bronchi the cartilages become leſs regular in their form, and fewer. They no longer exhibit that annular form, but conſiſt merely of ſmall pieces, ſometimes ſeparate, and ſometimes united. As the ſubdiviſions are multiplied, the cartilages become leſs firm, and at laſt diſappear altogether, ſo that we find only a membranous ſtructure when we have traced the air-tubes as far as the eye can go.

The external ſurface of this fibrous membrane is ſprinkled behind with ſmall lightiſh brown and flattened bodies of very variable figure, round, oval, &c. Theſe are mucous glands, of which the excretory ducts open on the internal ſurface of the tube. They are ſmaller on the bronchi than in the trunk of the trachea, and they become more minute in proportion as the veſſels ramify. Their ſtructure ſeems to be very ſimple; one duct comes from each gland generally; but ſometimes two or three glands are united, and there the ducts are more numerous. The fibrous membrane exhibits none of theſe glands in the intervals of the cartilages, on its external ſurface. The inner ſurface of the membrane, in the ſame ſituation, correſponds to the mucous lining of the tube, from which it is ſeparated by numerous ſmall and cloſely arranged granular bodies, which are probably mucous glands. At the back part of the tube there is found, under the fibrous membrane, a ſtratum of tranſverſe fibres extended between the extremities of the cartilages, to which they are attached. Theſe are diſpoſed in ſmall faſciculi, have not the white aponeurotic appearance of the fibrous membrane, and ſeem to be real muſcular fibres. They are connected to the mucous lining by a looſe cellular tiſſue, and may be moſt advantageouſly ſeen by diſſecting away that membrane from the inſide. In what manner theſe fibres affect the phenomena that occur in the trachea we do not know. The longitudinal ones, that compoſe the fibrous membrane already deſcribed, have generally been regarded as of a muſcular nature: but their appearance by no means warrants this repreſentation. They poſſeſs conſiderable elaſtic power, ſo that the trachea, when extended, recovers itſelf very quickly and completely: this property is frequently brought into exerciſe in the living ſtate from the motions of the head and neck. The effect of the cartilaginous ſemi-circles, which are incorporated with this membrane, in preſerving the air-tubes permanently open, and the neceſſity of this arrangement to the execution of the reſpiratory functions, are too obvious to require any detailed illuſtration.

The mucous membrane, or the third conſtituent portion of the air-tubes, is the ſecond diviſion of that great mucous apparatus, called by Bichat *gaſtro-pulmonaire*. We trace its continuation from the pharynx into the larynx, through that cavity into the trachea and bronchi, to their ultimate ramifications. In the latter, it is ſaid to exiſt alone, or without the other two parts already mentioned: but the minuteneſs of the parts makes it difficult to aſcertain this point by direct examination, although ſuch a ſtructure would be favourable to that more intimate connection between the blood and air-veſſels, which is neceſſary to the chemical phenomena of reſpiration, according to the notions commonly entertained reſpecting theſe phenomena. The external ſurface correſponds behind to the tranſverſe fibres; and in the reſt of its extent to the fibrous membrane and cartilages, which latter project through it. The connecting medium which attaches it to all theſe parts is a cellular ſubſtance, admitting eaſily of ſeparation. The internal ſurface is ſmooth, and conſtantly lubricated by a mucous ſecretion: it forms the cavity of the air-tubes. The excretory canals of the mucous glands open on it in many parts very diſtinctly. In the back of the tube, where there is no cartilage, it exhibits numerous prominent and regular longitudinal folds: theſe extend into the bronchi and their ramifications. They are not produced by the contraction of any parts ſituated exteriorly, but exiſt when the membrane has been detached, and are not affected by tranſverſe extenſion of the tube: they ſeem to ariſe from ſmall fibrous columns forming a part of the ſtructure of the membrane.

For the organization of this membrane, we muſt refer to the general view exhibited in the article MEMBRANE. It is thinner, leſs ſpongy and ſoft, and more firmly attached in the trachea than in the larynx: the orifices of the mucous ducts are alſo ſmaller; in the bronchi it is ſtill more delicate, and this thinneſs increaſes as the tubes divide. In the natural ſtate it is white, ſo as to indicate that the capillary ſyſtem is not very clearly marked in it. Theſe veſſels are developed and become perceptible under numerous circumſtances, particularly in catarrhal affections, to which the pulmonary mucous membrane is very ſubject. The blood is then accumulated in the capillaries, and gives to the membrane a red colour, which it does not poſſeſs naturally.

It is ſuppoſed that this membrane compoſes entirely the air-cells, or veſicles of the lungs, in which the minute ramifications of the air-tubes end. If we impel air into the trachea, the whole lung becomes diſtended, and increaſes in volume in proportion to the quantity of air inflated. Attentive obſervation will then convince us that its whole ſubſtance is compoſed of ſmall cells, which we can readily diſcern on the ſurface. If the inflated lung be dried, or if the organ be diſtended with ſpirit of wine, and then cut, its whole ſubſtance is found to be compoſed of theſe cells, as well as its external ſurface. Injection with quickſilver will demonſtrate the ſame ſtructure. This gives to the lung, when cut or torn, a porous and ſpongy appearance throughout. The cells, when attentively ſurveyed on the ſurface of the lung, have a roundiſh figure, but their outline is often irregular. When inflated they meaſure $\frac{1}{5}$th or [illegible]th of a line in diameter. They communicate together in all directions ſo completely, by the ramifications of the air-tubes, that air might paſs eaſily from a ſingle cell into all parts of the lung; but the cells of the neighbouring lobules do not ſeem to have any direct communication.

The mucous membrane, in an extremely delicate ſtate, continued from the minute ends of the air-tubes, is ſuppoſed to compoſe theſe cells; but the minuteneſs of the objects renders our deſcription of them, excepting a few general facts, rather uncertain. Anatomy diſcovers to us rather a ſpongy net-work, filled with air, and formed by blood-veſſels croſſing in every direction, than any clear arrangement of diſtinct cells, connected to the bronchial ramifications, like grapes to their ſtalk, as they have been deſcribed and drawn by ſeveral anatomiſts.

In this view of the ſubject, the extent of ſurface of the mucous membrane muſt be enormous. Many attempts have been made to expreſs it in numbers. Hales makes the air-cells $\frac{1}{100}$dth of an inch in diameter; the ſurface of the air-tubes equal to 1035 ſquare inches; and that of the air-cells to 20,000. Keil eſtimates the number of the veſicles at 174,418,615, and the whole internal ſurface of the lung at 21,906 ſquare inches. Lieberkuhn carries his eſtimate of the ſurface as high as 1500 cubic feet. We mention theſe circumſtances only to ſhew the great extent of the mucous membrane, and not becauſe we place much faith in their accuracy. In reading deſcriptions of the minute ſtructure of the lungs, and, indeed, in all other analogous parts of anatomy, we ſhould always bear in mind the obſervation of Haller; "Ea fere hominum eſt infelicitas, ut omnis ultima rerum phyſicarum hiſtoria parum firma ſit, et ut altera illa, rerum geſtarum memoratrix, in mythices fines terminatur."

A mucous fluid conſtantly lubricates the whole of this ſurface. It is limpid, mild, and nearly inſipid, or ſlightly ſaltiſh, and but little tenacious in the natural ſtate. When free from air, it ſinks in water. It is produced in ſo ſmall a quantity, that it ſeems to be diſſolved in the air, and thus to paſs off inſenſibly in exſpiration, or to be taken up by the abſorbents. It is poured out much more abundantly under various circumſtances, and is altered in colour and conſiſtence: it is then expelled by the expiratory efforts which conſtitute cough. In children it has a reddiſh colour; and it is often rather livid in adults.

The watery vapour diſcharged from the lungs in exſpiration concurs in lubricating the ſurface of the air-paſſages. Whether there be any exhalation from the general mucous ſurface, in addition to the mucous ſecretion, ſeems a point hardly ſuſceptible of poſitive determination.

The pulmonary mucous membrane is the part in which the chemical phenomena of reſpiration are carried on; its ſurface is in contact with the air taken into the lungs. The latter fluid is the only one, in addition to its natural mucus, of which it can bear the contact. All other ſubſtances, even the cleareſt water, are immediately and powerfully rejected by it. In itſelf it poſſeſſes no power of expelling any irritating matter from its ſurface; but it excites the expiratory muſcles which act convulſively and repeatedly until the cauſe is removed.

The veſſels and nerves of the lungs are principally diſtributed on the air-tubes, of which they every where follow the courſe. The arteries of the trachea come from the inferior thyroideal; thoſe of the bronchi are derived immediately from the aorta, and are called the bronchial arteries. The latter ramify in conjunction with the air-tubes, and adhere cloſely to them: they are diſtributed chiefly on the internal membrane. Several branches are ſpent on the bronchial glands, and on the parietes of the pulmonary veſſels. Do they anaſtomoſe with the pulmonary artery? We ſhould be inclined to ſuppoſe that they do not, from conſidering that the two kinds of veſſels contain blood of different natures, and have altogether different offices. The bronchial arteries convey arterial blood for the nutrition of the lung; the pulmonary artery takes the venous blood, that it may be ſubmitted to the action of the air in reſpiration. Yet it has been aſſerted by ſeveral anatomiſts, that ſuch an anaſtomoſis does take place. The bronchial veins accompany the arteries: their trunks end in the vena azygos on the right ſide, and in the ſuperior intercoſtal vein on the left.

The par vagum furniſhes nearly all the nerves belonging to theſe organs: thoſe of the trachea come from it altogether. The nerves of the bronchi are derived from the pulmonary plexuſes formed principally by the par vagum, but partly alſo by branches from ſome ganglia of the great ſympathetic. As theſe nerves ſeem to be diſtributed entirely on the air-tubes, perhaps the epithet bronchia would be more proper for them than pulmonary.

The vaſcular ſyſtem of the lungs may be divided into three parts, diſtinct in their nature, properties, and the immediate object of their phenomena. The firſt is the pulmonary artery, or the end of the general ſyſtem of black blood; the ſecond, the pulmonary veins, or commencement of the general ſyſtem of red blood; and the third, the capillary ſyſtem intermediate to the two preceding. (See Circulation and Heart.) The pulmonary artery ariſes from the upper and anterior part of the right ventricle, in front of the origin of the aorta. It paſſes upwards and backwards, lying cloſe on the left ſide of the root of the aorta, and, after a courſe of about an inch and a half, divides into a right and left branch deſtined for the correſponding lungs. Theſe two diviſions ſeparate moſt widely at their origin, going off from the trunk at right angles, and hardly forming a ſenſible angle with each other. The ſeparation takes place on the left ſide of the aorta. The right trunk goes immediately behind the aorta and ſuperior vena cava, and follows a tranſverſe courſe to the right lung; the left has an analogous courſe on the left ſide of the body, but is much ſhorter than the right, on account of the latter paſſing behind the aorta and vena cava. Both are placed in front of the bronchi, and croſs the courſe at firſt, being directed a little from below upwards; but they are ſubdivided exactly like the bronchi, and follow their courſe, being cloſely connected to them throughout: the artery is generally placed above its correſponding air-tube. For the organiſation of this veſſel, we refer to the article Heart.

The pulmonary veins, ariſing from the capillary ſyſtem, follow a courſe analogous to that of the arterial diviſions. Theſe alſo accompany the air-tubes, and are ſituated under them. They unite gradually into larger and larger tubes, and form ultimately four conſiderable trunks, two belonging to each lung, and terminating in the left auricle of the heart. The ſuperior right pulmonary vein paſſes out of the lung below the bronchus, and goes with a little obliquity downwards: the inferior aſcends obliquely towards the auricle. The left veins have a ſimilar arrangement; one deſcends, and the other aſcends: they are more approximated than on the

the right ſide. For the organiſation of theſe veſſels, ſee Heart.

The capillary veſſels of the lung are diſtributed in infinite number through all parts of the organ, of the proper tiſſue of which they compoſe a very conſiderable ſhare. As they have no connection with the nutrition of the part, and perform no ſecretion, they give paſſage only to the blood, and are hence remarkably diſtinguiſhed from the general capillary ſyſtem. Theſe veſſels cover in vaſt profuſion the air-cells of the lungs; ſo that when they are injected with coloured fluids after death, the whole ſubſtance of the organ appears dyed of the peculiar colour. In them the blood is expoſed to the air, and converted from the dark or venous into the red or arterial ſtate.

The ſubſtance of the lungs, on ſuperficial examination, offers a ſoft ſpongy maſs, yielding eaſily to preſſure, and reſtoring itſelf afterwards to its original ſtate in an imperfect manner. When we view it more attentively, we obſerve on the ſurface ſmall whitiſh lines circumſcribing ſpaces of different figures, as triangular, quadrangular, &c. Theſe are called lobules of the lungs, and vary conſiderably in ſize as well as figure. They are again divided into other ſmaller parts. Theſe lobules are all connected together by a looſe and ſoft cellular ſubſtance, which never contains any fat; and the ſame ſubſtance unites the reflected pleura to the external ſurface of the lung. If we tear the ſubſtance of the organ, and inflate it, the air fills the cells of this cellular texture, and makes it more ſenſible: it is alſo in ſome caſes rendered more obvious, by being the ſeat of a watery depoſition, which conſtitutes anaſarca of the lungs. Its cells have no communication with the air veſicles, unleſs the latter be broken by inflation, as when we ſqueeze the air in them forcibly, they crack, and the air eſcapes into the cellular texture, uniting the lobuli. On the other hand, we might inflate the cellular ſubſtance diſtinctly from the air-cells.

Each lobulus of the lung conſiſts of a branch of the air-tube with a correſponding proportion of cells, a branch of the pulmonary artery and vein, a portion of the pulmonary capillaries of the bronchial veſſels and nervous ramifications, connected by the cellular ſubſtance already deſcribed.

The lymphatics of the lungs are numerous, and divided into a ſuperficial and deep-ſeated ſet: the former conſtitute a net-work on the ſurface of the lung, and communicate alſo with the latter. They paſs through numerous glands, called bronchial, placed on the trunks of the air-tubes and blood-veſſels, partly within, but chiefly without the ſubſtance of the lung. Other larger glands are ſituated about the diviſion of the trachea, and the abſorbents of the right and left lung communicate in them. Some abſorbents of the right lung terminate in the right abſorbent trunk; the reſt, with thoſe of the left, end in the thoracic duct, paſſing through glands on the ſpine.

The bronchial glands are large in ſize, and numerous in proportion to the lung; but they vary in both theſe reſpects in different ſubjects. Several of the ſmalleſt are found on the bronchi, within the ſubſtance of the lung. Their colour is the moſt remarkable of their properties: in the adult it is a deep livid or black. Their conſiſtence is rather ſoft, and a coloured fluid may be expreſſed from them, when cut or divided. It is now clearly aſcertained that theſe bodies belong to the lymphatic ſyſtem. Anatomiſts formerly conceived that they ſecreted a particular fluid, and poured it into the bronchi. We are quite ignorant of the cauſe of their peculiar black colour.

The lung, then, is made up of the tiſſues juſt deſcribed, covered on the ſurface by the very thin and tranſparent pleura pulmonalis, which is connected to the organ by cellular ſubſtance, and gives it the ſmooth external ſurface.

Developement of the Lungs.—The fœtus has no reſpiration: from the circumſtances under which it is placed in the uterus, it muſt obviouſly be altogether precluded from exerciſing that function; but it begins immediately after birth: hence the lungs, formed nearly as ſoon as the principal organ of circulation, poſſeſs, at a very early period, a conſiderable developement and well-marked form. Their organiſation, too, is perfect, or at leaſt they are capable of executing their functions, before the time at which they naturally come into action: for there are inſtances of children born long before the end of the ninth month, as, for inſtance, at the ſeventh, or even ſooner, who have been preſerved alive by great care. In the early periods their colour is reddiſh; they then aſſume a ſlightly tawny hue, which is continued till the time of birth, and is not even changed by reſpiration, although the admiſſion of air into the organs at that time is followed by the entrance of a larger quantity of blood.

The lobuli are very diſtinct in the fœtus, and eaſily ſeparable: the connecting ſubſtance appears to be more copious. Although the lungs are ſmall in a fœtus at full time, compared to thoſe of a child who has breathed, we cannot ſay, as ſome anatomiſts repreſent, that they are extremely diminutive, and confined to the back of the cheſt. As they are at this time entirely free from air, they poſſeſs a denſity, which makes them ſink inſtantly in water, when plunged into it either entire or in ſlices. They are penetrated by much leſs blood than after breathing has begun, and therefore reduced almoſt entirely to their ſolid and organiſed contents: they form at this time about $\frac{1}{70}$th of the weight of the whole body.

As the function of reſpiration, which commences at the moment of birth, goes on afterwards uninterruptedly, and as the phenomena are as regular and perfect at this time as in more advanced age, we have no reaſon to expect that the intimate ſtructure of the organ, that is, the arrangement of the different component tiſſues, will be different at that age from what we know of it in the adult: but the vaſcular trunks belonging to theſe parts exhibit ſome peculiarities, of which the details will be found in the articles Heart and Circulation.

Breathing begins immediately after birth; the enlargement of the cheſt occaſions the lungs to be diſtended with air, and conſequently to become ſpecifically lighter; a greater quantity of blood paſſes through them, and thus they acquire greater abſolute weight. The increaſe of volume muſt be limited by the capability of enlargement in the cheſt; and this cannot be very conſiderable immediately on birth. This enlarged ſize is not, therefore, ſufficiently marked, to be relied on as a proof that reſpiration has begun. It is a well-known fact, which we have already ſtated, that the lungs of an individual, who has breathed, ſwim in water, whether they be immerſed entire or in ſlices. This is a property remarkably contraſted with what takes place under the ſame treatment before birth. A criterion has been ſought for in this ſource, to determine, in doubtful caſes, whether a child has been born dead or alive: and the conſideration is a highly important one, from the influence it may produce on medical opinions, in caſes of ſuſpected child-murder. We ſhall only obſerve here, that the convulſive attempts to eſtabliſh reſpiration, although not ſucceſsful, may introduce air enough into the lungs to make them buoyant in water; that attempts to inflate them, in order to preſerve the child, or after it has died, may have the ſame effect; that the diſengagement of air by putrefaction

tion may thus make them ſpecifically lighter than water; not to mention, that the child may have breathed and died afterwards: ſo that the mere naked circumſtance of the lung ſwimming is altogether an inſufficient proof that the child has been murdered; and to condemn a mother to death on ſuch grounds, exhibits a degree of ignorance and barbarity worthy only of the dark ages.

The increaſe of abſolute bulk in the lungs after birth is a phenomenon very worthy of being remarked. We have ſtated already, that theſe organs in the fœtus, at full time, are $\frac{1}{70}$th of the body. According to the reſearches of ſome German and French anatomiſts, they are no more than $\frac{1}{35}$th, or $\frac{1}{37}$th in a child who has breathed. There may be ſome variation in this point, but the organs are never ſo light as to approach at all to the proportion which they exhibit before birth; a fact which is highly important in its application to queſtions of ſuppoſed infanticide.

The colour of the lungs does not remain through life the ſame as at the time of birth. In the earlier years it has ſtill the reddiſh, mixed with a tint of yellow, which we have already mentioned. After the twentieth year the livid or black ſpots appear, and become more numerous as age advances.

Phyſiology of the Lungs.—Two very different kinds of phenomena take place in the lungs. The firſt are entirely mechanical, and relate to the motions of the ſides of the cheſt, by which the cavity is enlarged or diminiſhed; and to the dilatation or contraction of the air-cells, and the admiſſion and expulſion of the air, which are conſequent on theſe motions. Theſe have been already conſidered in thoſe parts of the preſent article which relate to the motions of the thorax. The phenomena of the ſecond kind are purely chemical, and conſiſt of the various alterations which the reſpired air undergoes, of the changes effected in the compoſition of the blood, &c. For an account of theſe, the reader is referred to Respiration, and Heat, *Animal.*

Theſe two diviſions of the reſpiratory phenomena belong reſpectively to the two great claſſes of vital proceſſes; the animal and organic. The motions of the cheſt are performed by voluntary muſcles, and conſequently are ſubject to the influence of the brain: hence a ſection of the medulla ſpinalis above the origin of the phrenic nerve, or a diviſion of the nerves which ſupply the muſcles of reſpiration, immediately annihilates theſe motions. Commonly, indeed, the motions of the cheſt are performed ſpontaneouſly, that is, without any exertion of the will; and they go on during ſleep, when the action of all voluntary organs is ſuſpended. But an act of the will can accelerate, retard, or otherwiſe modify the movements of the cheſt; and many of the muſcles concerned aſſiſt in moving the trunk, on occaſions that have nothing to do with reſpiration. The changes of the blood, on the other hand, go on in the capillaries, and are performed without our conſciouſneſs: the brain has no influence on them. The reſpiratory functions, then, offer the point of union of the animal and organic lives, in which theſe may reciprocally influence each other.

The chemical and mechanical phenomena of reſpiration are in a ſtate of mutual dependence: the interruption of one is always quickly followed by the ceſſation of the other. Without the former, the latter would have no materials to act upon. If the mechanical phenomena were interrupted, the blood would no longer be fit to excite the brain; and that organ could not influence, in the proper manner, the intercoſtal muſcles of the diaphragm: hence theſe muſcles would become inactive, and even the mechanical phenomena muſt ceaſe.

The heart does not influence theſe two kinds of phenomena in the ſame way.

The heart of black blood has obviouſly no power over the mechanical phenomena of the lungs; but it is eſſentially concerned in producing the chemical phenomena, as it ſends to the organ the fluid which derives certain properties from the air, and imparts others to it. Thus, when the functions of the auricle or ventricle of black blood, or of the great venous trunks, are interrupted, as by a wound, or a ligature applied in experiments, the chemical phenomena are at once annihilated; but the dilatation and contraction of the cheſt ſtill goes on. No blood arrives at the left ventricle, and conſequently the requiſite motion cannot be imparted to the brain: hence its functions are ſuſpended, and conſequently the intercoſtal muſcles and diaphragm ceaſe to act.

In the caſe of a wound affecting the auricle or ventricle of red blood, the aorta, or its great branches, when a ligature is artificially applied to the latter, or an aneuriſm burſts, &c. the functions of the lungs ceaſe in the following order: 1. No more impulſe communicated to the brain; 2. No more motion of that organ; 3. No more action exerted on the muſcles, and conſequently no more contraction of the intercoſtals and diaphragm; 4. No more mechanical phenomena. Without the latter, the chemical phenomena cannot take place: in the foregoing caſe, they were ſtopped for want of blood; in this, they ceaſe from the interruption in the ſupply of air.

The preceding obſervations are derived from the Recherches Phyſiologiques of Bichat. In the 6th, 7th, 8th, and 9th articles of the ſecond part of that work, he has entered at length into the conſideration of the influence of the lungs on the heart, the brain, and the organs of the body in general; of which ſubjects he has given more clear and connected views than any other phyſiologiſt. We ſhall, therefore, avail ourſelves of his labours in this concluding diviſion of the preſent article.

Influence of the Death of the Lung upon that of the Heart.—The ceſſation of action in the lungs may begin either in the mechanical or the chemical phenomena. A wound expoſing them extenſively on both ſides of the cheſt, and producing their ſudden collapſe; a diviſion of the ſpinal marrow ſuddenly paralyſing the intercoſtal muſcles and diaphragm; are caſes in which the death of the lungs begins in the mechanical phenomena. It commences in the chemical, in aſphyxia from noxious gaſes, from ſtrangulation, ſubmerſion, expoſure in vacuo, &c.

The heart's action can be interrupted by the ceſſation of the mechanical phenomena of the lungs only in two ways: 1. Directly, if the blood meets in the lungs with a real mechanical obſtacle to its circulation; 2. Indirectly, becauſe where the mechanical action of the lungs ceaſes, they no longer receive air, which is neceſſary to their chemical phenomena, the ceſſation of which interrupts the action of the heart.

All phyſiologiſts have admitted that the pulmonary circulation is interrupted in the former of theſe two ways. They have conceived, that where the lung is not diſtended, its veſſels are folded and compreſſed, and therefore tranſmit the blood with difficulty: and by this explanation, derived from hydraulic phenomena, they have accounted for the death which enſues, where expiration is too long continued.

Goodwyn proved that a ſufficient quantity of air remained in the pulmonary veſicles to allow mechanically the paſſage of the blood; and, conſequently, that protracted expiration is not fatal in the way commonly ſuppoſed. (Connection of Life with Reſpiration, &c.) An experiment, which any one may very eaſily perform in his own perſon, will prove that point very eaſily. Let him exſpire as fully as poſſible, and not inſpire again: the pulſe is not changed, and conſequently the circulation through the lungs is not impeded. But the numerous and varied experiments of Bichat place the ſubject beyond all doubt. Exhauſt, ſays he, the lungs of an animal, by means of a ſyringe inſerted in the trachea, and open the carotid artery. Here the circulation ought to be ſuddenly interrupted, according to the common ſuppoſition, ſince the pulmonary veſſels are reduced from their ordinary degree of diſtention to the greateſt poſſible collapſe and folding: yet the blood continues for ſome time to be forcibly thrown out of the opened artery, and muſt conſequently circulate through the lung in this ſtate of extreme collapſe. The ſame circumſtance is obſerved when the lungs collapſe, in conſequence of the thorax being opened on both ſides; even if, in addition to this collapſe, we exhauſt the air more effectually with a ſyringe.

The pulmonary circulation is continued, and even performed with facility, when collections of water, pus, or blood, exiſt in the cheſt, and diminiſh, in a very conſiderable degree, the air-cells of the lungs; and when, conſequently, the angles and folds of the veſſels, if they are found at all, muſt be very conſiderable. We may conclude, then, that the interruption of the mechanical phenomena of reſpiration does not ſtop the heart's action directly; but that it operates indirectly, by cutting off the ſupply of the material, which is neceſſary for the exerciſe of the chemical phenomena.

The death which ſucceeds to protracted inſpiration has been aſcribed to the mechanical diſtention of the pulmonary veſſels by the air, which has been ſuppoſed to impede the circulation through them. But this explanation is as ill-founded as that which we have juſt conſidered. Diſtend the lungs of an animal by injecting a large quantity of air, and confine this by a ſtopcock faſtened in the trachea; then open the carotid artery. The blood continues to flow for ſome time with its natural freedom.

Two opinions have been entertained concerning the manner in which the interruption of the chemical phenomena of the lungs produces a ceſſation of the heart's action. According to Goodwyn, the black blood does not ſtimulate the left ventricle; ſo that, in his manner of viewing aſphyxia, death takes place, becauſe that cavity ſends nothing to the different organs. Its ſource, therefore, is excluſively in the heart. Bichat conceives, that when the chemical phenomena of the lungs are interrupted, there is a general affection of all the organs: that the black blood carries to every part debility and death, ſo that the organs do not ceaſe to act becauſe they receive no blood, but becauſe they receive no red blood. The effects of the contact of black blood on the organs of the body will be illuſtrated preſently; we ſhall conſider here the phenomena of its contact with the parietes of the heart.

Many circumſtances ſhew that the black blood is capable of ſtimulating the left ventricle, ſo as to excite it to contraction. If this were not the caſe, death ſhould commence in aſphyxia with the ceſſation of the heart's action, and the annihilation of the functions of the brain ſhould be ſecondary. But, kill an animal by ſtopping the trachea, by placing it in vacuo, by drowning or immerſion in noxious gaſes, &c. and you will conſtantly obſerve, that the animal life is firſt interrupted, that the ſenſations, motions, and voice are ſuſpended, ſo that the animal is dead externally, while the heart ſtill beats and the pulſe is kept up for ſome time. The different organs, therefore, do not ceaſe to act in aſphyxia, becauſe the heart ſends them no blood, but becauſe it ſends a kind of blood which is not ſuited to them.

Let the trachea of an animal be ſtopped and an artery opened, the blood iſſuing from the latter is at firſt red, then grows gradually darker, and at laſt is black venous blood. Nevertheleſs, it is ſtill expelled for ſome time with conſiderable force. If the lungs be exhauſted by a ſyringe, previous to cloſing the trachea, and an artery then opened, black blood comes from it immediately, without going through the ſhades mentioned before, and a tolerably ſtrong jet is kept up for ſome time. If the black blood did not poſſeſs the power of exciting the left ventricle, its flow ſhould be ſuddenly interrupted in this caſe, where it can undergo no change from the lung, and exiſts in the aorta in the ſame ſtate as in the venæ cavæ.

It is moreover ſtated by Bichat, that he has re-excited the contractions of the left ventricle, after they had ceaſed in various kinds of violent death, by injecting black blood through one of the pulmonary veins. It is obvious too, that when ſuſpended reſpiration is reſtored by inflating the lungs, the left ventricle muſt firſt propel the black blood with which it is loaded, before the red blood can arrive at the lungs. The heart of red blood has, therefore, the power of impelling black blood into all the organs; and in this way we explain the peculiar colour of the different ſurfaces in aſphyxia.

The mere contact of black blood has no more ſenſible action on the internal ſurface of the arteries than on that of the heart. If, when the trachea is cloſed, an artery of the foot be opened, the blood is propelled from it for ſome time with the natural force.

"From theſe conſiderations and experiments we may conclude," ſays Bichat, "that the black blood has the power of exciting the internal ſurface, and determining the action of the heart and arteries; and that if no other cauſe interfered with their functions the circulation might be continued, not, perhaps, with equal force, but at leaſt in a very ſenſible manner. What then are the cauſes which interrupt the circulation in the heart of red blood and in the arteries, when the lung tranſmits to them only black blood? For when the latter has flowed for ſome time, the jet is gradually weakened, and at laſt entirely ceaſes: if the ſtopcock fixed in the trachea be now opened, it is again ſpeedily reſtored. I believe that the black blood acts upon the heart as upon all other parts, as we ſhall ſee that it influences the brain, the voluntary muſcles, the membranes, &c.; that is to ſay, by penetrating its tiſſue, by debilitating each individual fibre. I am well convinced, that if black blood could be circulated in the coronary veſſels, while the red ſhould paſs as uſual through the left auricle and ventricle, the circulation would be interrupted almoſt as quickly as in the preceding caſes." We conclude then, in general terms, and without attempting to determine how this takes place, that the heart's action ceaſes when the chemical phenomena of the lungs are interrupted, becauſe the black blood, which penetrates its muſcular fibres, is not capable of keeping up their action.

In this view of the ſubject, the right ventricle will be as much affected as the left, ſince the black blood is diſtributed equally to the fibres of each. Yet the latter ceaſes to act firſt, and this is ſo conſtantly and well known a fact, that the right ſide of the heart has been called the ultimum moriens. This ariſes, as Haller has already clearly explained, from the circumſtance of the right cavities being longer excited than the left. (See HEART, and CIRCULATION.) It does not prove that the left ventricle dies firſt in aſphyxia. If that were the caſe, the left auricle and ventricle ſhould be diſtended with blood after death, and this diſtention ſhould be propagated from them into the pulmonary veins and right ſide of the heart; that is to ſay, the congeſtion of blood ſhould begin in the reſervoir which firſt ceaſes to act, and it ſhould be propagated from that into the others. The examination of animals, who have periſhed from aſphyxia, ſhews us, on the contrary, that the cavities of red blood and the pulmonary veins contain but a ſmall quantity of black blood in compariſon with that which diſtends thoſe of the oppoſite ſide; that the point at which the blood has ſtopped is principally in the lung, from which we are to trace its ſtagnation in the whole venous ſyſtem; and that the arteries contain as much in proportion as the correſponding ventricle, ſo that death cannot be ſuppoſed to have begun in it rather than in any other part.

Bichat ſtates afterwards, that he cannot entirely reject the notion of the leſs aptitude of the black blood to ſtimulate the left ventricle. When an artery is opened, a ſtopcock being fixed in the trachea and cloſed, the jet of blood is gradually weakened; open the ſtopcock, and the blood becomes again immediately red, and is thrown out more forcibly. This change is too ſudden to admit of our accounting for it by the red blood penetrating the tiſſue of the heart. Yet it may happen from the powerful motions of inſpiration and exſpiration which the animal makes as ſoon as air enters the cheſt. For if an artery be opened, and reſpiration thus hurried, the jet of blood will be manifeſtly increaſed. On the whole, therefore, even if it be allowed that red blood is a more powerful ſtimulus to the heart than black, the exceſs muſt be very trifling.

In connection with this ſubject, we may conſider the explanation of the remarkably diſtended ſtate, in which the pulmonary artery, the right cavities of the heart, and the venous ſyſtem are found in inſtances where death commences in the chemical phenomena of the lungs, compared with the comparatively empty condition of the ſyſtem of red blood. The phenomenon is ſo remarkable as to have attracted the attention of all who have opened the bodies of animals killed by aſphyxia; it has been commonly explained by the folds of the pulmonary veſſels, which we have already conſidered.

The lungs are found in two very different ſtates, according to the manner in which life ends: when death is inſtantaneous, they are not loaded with blood; the auricle and ventricle of black blood, the pulmonary artery, and the general venous ſyſtem, are not remarkably diſtended. On the contrary, when the chemical phenomena of reſpiration are ſlowly deſtroyed, when an animal has been kept as long as poſſible in the diſtreſs and anguiſh which attend interruption of the functions of the lungs, theſe organs are extremely loaded with blood, and diſtended to a volume very far exceeding that which they preſent in the other caſe. In whatever condition the lungs of an animal, which has periſhed by aſphyxia, may be found, whether they be loaded or empty, and conſequently whether death have been brought on ſlowly or ſuddenly, the vaſcular ſyſtem of black blood is always full of this fluid, particularly about the heart; there is conſtantly a great difference in this reſpect between it and the vaſcular ſyſtem of red blood, and conſequently the principal obſtacle to the circulation is in the lung.

Bichat explains this phenomenon from certain conſiderations connected with the blood, the lung, and the heart.

1. The black blood circulating in the arteries is incapable of furniſhing to the organs of ſecretion, exhalation, and nutrition, the various materials neceſſary for the exerciſe of thoſe functions; or if it conveys the materials, it cannot excite the organs. Hence, the venous ſyſtem receives an unuſually large quantity of blood, as all that portion, which is ordinarily removed by the functions juſt mentioned, enters it; and the difficulty of the paſſage through the lungs is proportionally augmented. All obſervers have been ſtruck by the great abundance of blood found in the veſſels in theſe caſes.

2. The lung is no longer excited by red blood: the bronchial veſſels carry black blood to it, and hence its powers are enfeebled, as thoſe of the heart are by the ſame fluid conveyed to it by the coronary arteries Again, the pulmonary capillary ſyſtem contains nothing but black blood. That the tonic powers, by which the circulation is carried on in thoſe veſſels, muſt be much depreſſed from this cauſe, cannot be doubted. Moreover, the habitual excitation of the mucous ſurfaces by the atmoſpheric air is interrupted; and this muſt aſſiſt in lowering the tonic powers.

3. The auricle and ventricle of black blood act more weakly, and are leſs capable of ſurmounting any reſiſtance in the lung in conſequence of their fibres being penetrated by black blood. They can no longer reſiſt the blood brought by the venæ cavæ, and become diſtended by it.

Theſe conſiderations ſeem to account ſatisfactorily for the diſtention of the ſyſtem of black blood in aſphyxia; we have next to explain why the ſyſtem of red blood contains a quantity comparatively ſo ſmall. As the obſtacle exiſts in the lungs, a ſmaller quantity arrives at the left ſide of the heart. The natural ſtrength of the left ventricle and the arteries exceeds that of the right and the veins; conſequently the former can more eaſily overcome the reſiſtance of the capillaries of the body in general, than the latter can that of the pulmonary capillaries. Again, there is only one cauſe of retardation in the general capillary circulation, *viz.* the contact of black blood with the organs; while there is added to this cauſe in the lungs, the abſence of the habitual excitation produced by the atmoſpheric air. Thus, we find in the lungs more reſiſtance to the blood brought by the veins, and leſs force to overcome that reſiſtance; while in the body in general the obſtacles at the junction of the arteries and veins are more feeble, and the force tending to overcome them is greater.

Although the general capillary ſyſtem offers leſs reſiſtance to the arteries, than the pulmonary capillaries do to the veins in aſphyxia, yet there is a manifeſt obſtruction even here; and it gives riſe to two remarkable phenomena. Black blood is collected in the arteries in a much greater quantity than uſual, although in a ſmaller proportion than in the veins; hence injection ſucceeds badly in ſuch ſubjects. The accumulation of black blood in the extremities of the arteries gives a livid colour to all the ſurfaces of the body, and a bloated appearance to the various parts, as the face, tongue, lips, &c. Theſe two phenomena indicate a congeſtion of black blood in the arterial extremities, as the analogous appearances of the lungs denote a difficulty of paſſage through the pulmonary capillaries, where indeed the congeſtion is much more manifeſt, becauſe the ſyſtem is concentrated within a ſmall ſpace, while the other is ſpread over the whole body.

Influence which the Death of the Lung produces on that of the Brain.—The black blood acts upon the brain as it does on the heart; that is, by penetrating its tiſſue, and depriving it of the excitation neceſſary for keeping up its action. What we have ſaid concerning the heart is therefore equally applicable to this ſubject. The experiments of Bichat on this point have been very numerous and diverſified. He firſt transfuſed through a tube the blood of the carotid of one dog into the carotid of another: this does not hurt the animal if a vein be opened to obviate plenitude of the veſſels.

It proves that the contact of extraneous red blood does not injure the cerebral functions. He then opened the jugular vein and carotid artery of a dog, received the blood of the former in a ſyringe heated to the temperature of the body, and injected it into the latter. The animal was almoſt immediately agitated; the reſpiration was hurried, and the diſtreſſing kind of ſuffocation that belongs to aſphyxia was produced. Soon all the ſymptoms of the latter ſtate appeared; the animal life was entirely ſuſpended; the heart ſtill continued to beat, and the circulation went on for half an hour, at the end of which time the organic life alſo was extinct. This experiment was often repeated, and invariably with the ſame reſult: about ſix ounces of black blood were injected. If the point of the ſyringe was inſerted into the vein, ſo as to draw up the blood without any poſſibility of its coming in contact with the air, the reſult was the ſame, except that death came on rather more ſlowly. Various other ſubſtances, ſuch as ink, oil, wine, water coloured blue, urine, bile, mucous fluids, produced the ſame effects. That the fatal effects ariſe in theſe caſes from the action of the black blood, &c. on the brain, and not on the internal ſurface of the arteries, is proved by injecting them into the crural artery; the injection is never mortal, although numbneſs and even paralyſis generally follow. If blood be taken from the carotid artery of an animal who is ſuffering aſphyxia, and injected into that of another, the ſame effects with thoſe already mentioned are produced. Alſo, if the carotids of two dogs are united by a ſilver tube, ſo that the heart of the one ſends its blood to the brain of the other, and a ſtopcock be placed in the trachea of the former, no bad effect is produced, ſo long as that remains open. Cloſe the ſtopcock, and black blood will be ſent inſtead of red. Now, the dog whoſe carotid receives this blood becomes confuſed and agitated, drops his head, and loſes his ſenſes; but theſe phenomena come on more ſlowly than when black blood taken from the venous ſyſtem is injected into the artery. If the transfuſion be ſtopped, the ſymptoms of aſphyxia may go off, and the animal recover; but death invariably follows the injection of black blood with a ſyringe.

In ſumming up his experiments, Bichat concludes, that the nature of the principles contained in the black blood render it either incapable of exciting the action of the brain, or actually injurious to the organ; but he cannot decide whether its influence is exerted negatively or poſitively.

He proceeds to make ſome intereſting obſervations on the nature and treatment of aſphyxia. "We might conclude," ſays he, "from the above-mentioned facts, that the beſt mode of treating thoſe who are ſuffering from aſphyxia, would be to impel into the brain red blood, which is its natural ſtimulus. Two points of time ſhould be diſtinguiſhed in aſphyxia; 1, that in which the central functions alone are ſuſpended; 2, when the circulation as well as the movements of the cheſt have ſtopped; for, in this affection, the animal life is firſt ſuddenly extinguiſhed, and the organic ceaſes after a certain interval. In the firſt of theſe periods, the transfuſion of red blood towards the brain, from the carotid of another animal, gradually re-animates the powers of motion; the cerebral functions are partly reſtored, and the arrival of blood in the brain is often announced by ſudden agitations of the head, eyes, &c.; but this improvement ſoon diſappears, and the animal relapſes if the cauſe continues, as for example, if the ſtopcock in the trachea remains ſhut. On the other hand, if the ſtopcock be opened in this firſt period, the arrival of freſh air in the lungs almoſt always gradually re-animates theſe organs. The blood aſſumes the red colour, and is ſent in that ſtate to the brain, and life is reſtored without transfuſion, which is completely ineffectual in the ſecond period of aſphyxia, that is, when the organic movements, particularly thoſe of the heart, are ſuſpended. The transfuſion of red blood towards the brain does not, therefore, afford us any remedy in the caſe of aſphyxia. Neither does it ſucceed after the injection of venous blood into the brain by means of a ſyringe, which is invariably fatal. Aſphyxia produced by injecting blood taken from the vein into the brain is more prompt and certain, than that occaſioned by the gradual change of the red into black blood, conſequent on interrupted reſpiration; and the nature of the two caſes is manifeſtly different."

The phenomena of aſphyxia, as obſerved in the human ſubject, coincide very well with what is obſerved in experiments on animals. In all caſes the brain is firſt affected, its functions are annihilated, and the animal life, particularly ſo far as regards the ſenſes, ceaſes; the internal functions are ſubſequently arreſted. When aſphyxia is produced in an animal with an artery open, it is curious to obſerve how the affection of the brain coincides with the change of colour in the blood, while the energy of the heart is unabated. Moſt of thoſe who have been expoſed to aſphyxia, and have eſcaped ſuffocation, have experienced only a general kind of benumbing or paralyſis, the ſeat of which is manifeſtly in the brain; while all in whom the pulſe and heart have ceaſed to beat, certainly die. Almoſt all who have recovered ſay, that they felt firſt more or leſs violent pain in the head, produced probably by the firſt contact of black blood with the brain. Bichat conſiders the common notions of the effects of charcoal vapours on the head, and the expreſſions concerning the heavineſs, giddineſs, &c. produced by them, as ſtrong proof that the firſt influence is in fact exerted on the brain. He obſerves further, that many individuals who have recovered from aſphyxia produced by this cauſe, exhibit, for a longer or ſhorter period, various affections of the intellectual functions and voluntary motions, as for inſtance confuſion of ideas, and unſteady motions of the lower limbs; the ſame effects, in a ſmaller degree, which apoplexy produces more ſenſibly. Convulſive motions have ſometimes taken place almoſt immediately after expoſure to mephitic vapours; and a pain in the head has often laſted many days after the diſappearance of the other ſymptoms.

From the foregoing conſiderations, Bichat deduces the following concluſions; 1ſt, that when the chemical phenomena of the lungs are interrupted, the black blood acts upon the brain as upon the heart, that is, by penetrating its tiſſue, and thereby depriving it of the excitation neceſſary to its action; 2dly, that its influence is much more promptly exerted on the former than on the latter of theſe two organs; 3dly, that the inequality of their influence determines the difference obſerved in the ceſſation of the two lives in aſphyxia, where the animal always ceaſes before the organic. Hence we may infer, how unfounded the opinion is, that in thoſe who are executed by the guillotine, the brain ſtill continues to live ſome time, and that ſenſations of pleaſure and pain may ſtill be referred to it. The action of this organ is intimately connected to its double excitation; 1ſt, by the motion, and 2dly, by the nature of the blood which it receives. As this excitation is ſuddenly interrupted in that mode of death, all feeling is as ſuddenly ſuſpended.

Influence of the Death of the Lung on that of the Organs of the Body in general.—Bichat commences his view of this ſubject by examining the changes of colour which the blood undergoes when the chemical phenomena of the lungs are interrupted. He found the beſt method of obſerving theſe changes to be by fixing a ſtopcock in the trachea of an animal, by which the quantity and kind of air introduced into the lungs can be regulated, and placing a ſmall tube with a ſtopcock in an artery, as the carotid or crural, which enabled him to aſcertain how the blood was altered.

1. When the ſtopcock is cloſed immediately after an inſpiration, the blood grows darker in thirty ſeconds; it has acquired a deep tint in a minute, and it poſſeſſes entirely the appearance of venous blood in a minute and a half, or two minutes.

2. The production of the black colour takes place more quickly by ſeveral ſeconds, if the ſtopcock be ſhut after exſpiration, particularly if it has been a complete one.

3. If the air be drawn out of the lungs by a ſyringe, the blood becomes immediately black: twenty or thirty ſeconds are ſufficient for the change. No ſucceſſive gradations of colour are obſerved.

4. If the lungs be extended by injecting air into them, and cloſing the ſtopcock, a longer time is neceſſary for changing the blood into the black ſtate: three minutes will then be required.

Theſe phenomena are obſerved in the paſſage of the animal from a ſtate of aſphyxia to death: a ſeries of an oppoſite nature is ſeen when it is reſtored from aſphyxia to life.

1. When the ſtopcock, after being cloſed for ſome minutes, is opened, the animal immediately performs ſix or ſeven great inſpirations and exſpirations. A jet of red blood ſucceeds the black, which was flowing before; and the interval between the two is at moſt thirty ſeconds. There is no ſucceſſive change of tints, but a certain and decided alteration.

2. If a ſmall quantity only of air be admitted, the change of colour is leſs conſiderable.

3. If freſh air be injected, and the ſtopcock then cloſed, the blood becomes red, but leſs manifeſtly than when the air is admitted by voluntary reſpiration: in the latter caſe the animal firſt expels the air that had become ſpoiled.

4. If the air incloſed in the lung be drawn out by a ſyringe, and freſh air injected, the change of colour is effected more rapidly than in the preceding caſe.

5. When the lung is expoſed by cutting through the ribs, the circulation is continued for a certain time. If it be alternately diſtended and emptied by means of a ſyringe, the red and black colours are ſtill produced ſo long as the circulation is kept up.

From the rapidity with which the blood, in theſe experiments, is changed from black to red on opening the ſtopcock, we cannot help concluding that the principle which cauſes this alteration paſſes directly from the lung into the blood, through the membranous lining of the air-cells. The acceleration of the motions of the heart in animals undergoing aſphyxia, as in the famous experiment of Hook, by injecting air into the trachea, muſt be referred to the red blood penetrating the fibres of the heart, and putting an end to the debility which the contact of black blood was producing. Yet this method will never re-produce the motions of the heart when they have been once annihilated by the contact of black blood. Bichat has often tried this without ſucceſs. The heart, ſays he, cannot be re-animated by the action of the air, unleſs the blood, coloured by that fluid, could penetrate the organ. When the circulation is ſtopped, how can this take place?

Hydrogen and carbonic acid gaſes were employed in reſpiration by filling bladders with them, and fixing them to the tube in the trachea. The bladder is alternately diſtended and emptied as the animal exſpires and inſpires. He is at firſt tolerably quiet, but in about three minutes begins to be agitated; reſpiration becomes hurried and troubled, the blood flowing from an artery grows darker, and is black at the end of four or five minutes. There was very little difference in the time required for the change, or intenſity of the colour, whichever of the two gaſes was employed.

The reaſon why the change of colour takes place more ſlowly when theſe bladders are adapted to the ſtopcock, than when the latter is cloſed, ſeems to be, that the air contained in the trachea and its branches is repeatedly thrown from the lung into the bladder, and *vice verſâ;* ſo that its whole reſpirable proportion is ſucceſſively preſented to the blood. This motion cannot take place in the latter caſe; ſo that as ſoon as the pure part of the air contained in the bronchial cells is exhauſted, the blood is no longer converted into the red ſtate, although the trachea and its large diviſions ſtill contain a conſiderable quantity of air capable of ſerving the purpoſes of reſpiration. It appears that the converſion of the blood goes on only at the extremities of the bronchial ramifications, and that the internal ſurface of the large air-veſſels has no connection with this phenomenon.

We have already ſeen that the action of the heart continues for ſome time after the chemical phenomena of the lungs have been interrupted; the arterial circulation is therefore ſtill maintained, although the arteries contain a different fluid from that which is natural to them; and the organs of the body, accuſtomed only to the red blood, become penetrated, in conſequence of this circulation, by black blood. Bichat has proved this by expoſing various parts in an animal, while the ſtopcock in its trachea was cloſed, and the animal was conſequently undergoing aſphyxia. He has examined in this way the muſcles, the nerves, the ſkin, mucous and ſerous membranes, and the granulations of wounds, and found that the black blood penetrated them all, and produced more or leſs conſpicuous alterations in their colour, which was rendered either brown or livid. The phenomenon is very obvious in the ſkin, which always preſents more or leſs extenſive livid ſpots in aſphyxia. Theſe can only be explained by the exiſtence of an obſtacle to the tranſmiſſion of the blood in the general capillary ſyſtem: in the ſame way we account for the ſwelling of various parts, as the cheeks, lips, and head in general.

The black blood does not penetrate at all into ſome parts of the general capillary ſyſtem, and the natural colour is conſequently preſerved: in others it manifeſtly enters and is obſtructed, producing a dark colour at the part, and moreover a tumefaction, if it enters in large quantity: or, laſtly, it may paſs this ſyſtem and enter the veins. In the two former caſes the general circulation is arreſted in the capillary ſyſtem; in the latter, which is the more general, the courſe of the blood is ſuſpended in the capillaries of the lungs.

The fact that the black blood continues to be circulated for ſome time after the chemical phenomena of the lungs have been interrupted, explains a phenomenon, which muſt have been obſerved by all who are much employed in diſſections; *viz.* that in the dead body we meet with black blood only, even in the veſſels which naturally carry red blood. However death may be produced, the functions of the lungs are troubled in the laſt moments of exiſtence, and end before thoſe of the heart. The blood ſtill moves, although it no longer receives the influence of the air: it is therefore circulated black for a certain length of time, and remains in that ſtate in the organs, although the circulation is much leſs evident than in aſphyxia.

After having ſhewn that the interruption of the chemical phenomena of reſpiration prevents the black blood from being converted into the red ſtate, and that this black blood is circulated through the body by the ſtill ſurviving action of the heart, Bichat proceeds to ſhew that the black blood is not capable of maintaining the vital powers and activity of the organs, which are therefore killed by its contact. The red blood, he ſays, gives to the organs their natural and healthy excitation, by which their vital powers are ſupported. Poſſibly this effect may be produced by the combination of the different principles that colour it, with the various organs in which it is contained.

The organs of the animal and of the organic life have their actions terminated in different ways. The former, being entirely dependent on the brain, have their functions ſuſpended as ſoon as thoſe of the brain ceaſe. We have already ſhewn that the contact of black blood produces the latter effect almoſt inſtantly; conſequently the organs of ſenſation, locomotion, and the voice, muſt be ſuddenly paralyſed in aſphyxia. But the circulation of the black blood produces ſtill further effects: when it penetrates the nerves, it renders them incapable of keeping up the communication between the brain and the ſenſes on one ſide, and the locomotive and vocal organs on the other. The contact of the black blood with the organs themſelves alſo annihilates their action. Inject into the crural artery of an animal blood drawn from one of its veins; the motions are ſoon weakened very perceptibly, and ſometimes a momentary paralyſis is produced. The effect cannot be aſcribed to tying the artery, for that alone is often attended with no ſuch conſequence, whereas the reſult of injecting black blood is always the ſame, except indeed that it varies in duration and intenſity. Senſation is alſo manifeſtly ſuſpended in this experiment, but later than the power of motion. The effect is always produced, particularly if the injection of black blood be repeated three or four times at ſmall intervals.

The organs of the internal life being independent of the cerebral action, have not their functions arreſted, like thoſe of the external life, by the ſuſpenſion of that action. It is the contact of the black blood only that acts in this caſe, and conſequently the death of theſe organs has one cauſe leſs than that of the locomotive and vocal parts, &c. We have already explained the influence of the black blood on the organs of circulation, and have ſhewn how the heart ceaſes to act as ſoon as it is thoroughly penetrated by that fluid. Its circulation in the veſſels of the coats of the arteries and veins weakens thoſe tubes, and ſuſpends their action. It muſt be exceedingly difficult, if not impoſſible, to bring forward any ſtrict proof that the ſecretions, exhalation, and nutrition cannot derive from the black blood materials ſuited to their offices; for that blood does not circulate in the arteries long enough to admit of our making experiments on thoſe functions. We muſt rely, therefore, chiefly on the analogy of what happens in other parts, to prove that the organs of ſecretion, exhalation, and nutrition have their functions interrupted when black blood is ſent to them. This ſtatement is very much corroborated by the quantity of blood found in the veſſels of thoſe who have periſhed by aſphyxia; it is ſo large as to be very troubleſome in diſſecting ſuch bodies, which might naturally be expected when the uſual outlets of the ſecretions, &c. are ſtopped.

From the preceding conſiderations Bichat concludes, that when the chemical functions of the lungs are interrupted, all the organs of the body ceaſe to act ſimultaneouſly, in conſequence of the contact of black blood; that their death coincides with that of the heart and brain, although it is not derived immediately from that cauſe; that, if it were poſſible for theſe two organs to receive red blood, while black was ſent to the others, the functions of the latter would ceaſe, while thoſe of the former would be continued: in a word, that aſphyxia is a general phenomenon, taking place at the ſame time in all the organs, and not more decidedly marked in any particular one.

By reſuming and comparing what has been ſaid concerning the influence of the lungs on the heart, the brain, and the organs in general, we ſhall eaſily form an idea how all the functions ſucceſſively terminate, when the reſpiratory phenomena are interrupted. When the mechanical phenomena are ſuſpended; 1, there are no more chemical phenomena, for want of air to ſupport them; 2, no more action of the brain, for want of red blood to excite it; 3, ceſſation of the animal life, that is, of the ſenſations, locomotion, and the voice, becauſe the organs are no longer excited by the brain, nor by red blood; 4, ceſſation of the general circulation; 5, ceſſation of the capillary circulation, of ſecretion, abſorption, and exhalation, in conſequence of the organs of thoſe functions being no longer excited by red blood; 6, no more digeſtion, for want of ſecretion and excitation of the digeſtive organs, &c.

When the chemical functions of the lungs are interrupted, the phenomena of death ſucceed in a different order: 1, interruption of the chemical phenomena; 2, ſuſpenſion of the action of the brain; 3, ceſſation of the ſenſations, and of voluntary motions, conſequently of the voice, and the mechanical phenomena of reſpiration; 4, ſtoppage of the heart's action, and of the general circulation; 5, termination of the capillary circulation, of the ſecretions, exhalation, abſorption, and conſequently of digeſtion; 6, annihilation of animal heat, which is the reſult of all the functions, and which does not leave the body until every kind of vital proceſs is extinguiſhed. In whatever function death may begin, it always ends in this.

There is a very intimate connection between the brain and the lungs: as ſoon as the former ceaſes to act, the functions of the latter are interrupted. This phenomenon, which is conſtantly obſerved in warm-blooded animals, can happen only in two ways: 1, becauſe the action of the brain is directly neceſſary to that of the lung; or 2, becauſe the latter receives from the former an indirect influence through the intercoſtal muſcles and diaphragm, an influence which ceaſes as ſoon as the brain becomes inactive.

The lung can influence the brain directly only through the par vagum and the great ſympathetic nerve. Irritation of the former renders reſpiration hurried, but this is an effect produced by any conſiderable pain. Diviſion of one nerve of the eighth pair affects the breathing for a time: but this goes off, and the reſpiratory functions are then carried on with their accuſtomed regularity. If both nerves are cut, reſpiration is ſtill more hurried: it does not return to its ordinary rate, as in the preceding experiment, but continues laborious for four or five days, when the animal periſhes. Hence we ſee that the eighth pair is neceſſary to the pulmonary functions, and conſequently that the brain has ſome influence on theſe functions: but the agency is not a very active or important one, ſince the functions of the lung are continued for a long time without it, and conſequently reſpiration is not ſuddenly ſtopped, through its interruption in injuries of the brain. Experiments ſhew that the interception of the influence derived from the great ſympathetic is equally inadequate to interrupt the functions of the lungs.

Since the lung is not affected immediately from the interruption of the action of the brain, there muſt be ſome intermediate organs, through which the former is acted on by the latter. Theſe are the muſcles of reſpiration. Subject, by the nerves which they receive, to the immediate influence of the brain, they become paralytic as ſoon as the action of the latter has ceaſed. If the ſpinal marrow be divided between the laſt cervical and firſt dorſal vertebra, the intercoſtal muſcles are paralyſed, and reſpiration is carried on by the diaphragm only. If the phrenic nerves be cut, the diaphragm is rendered motionleſs, and the intercoſtals alone perform breathing. In either of theſe caſes life may be continued for ſome time. But if the phrenic nerves and the ſpinal marrow about the bottom of the neck be both divided; or, which comes to the ſame thing, if the ſpinal marrow be cut through above the origin of the phrenic nerves, all communication between the brain and the agents of reſpiration is ſuſpended, and death immediately follows. The difference of half an inch in the height at which the ſection is made is ſo important, that, if it be done at one point, the animal ſhall live fifteen or twenty hours, if half an inch nearer to the brain, he will die immediately. In the former caſe it is below, in the latter above the origin of the phrenic nerve: in the one inſtance reſpiration and conſequently life ceaſes, becauſe the diaphragm and intercoſtal muſcles can act no longer; in the other the diaphragm carries on the reſpiratory functions, and conſequently ſupports life for ſome time.

The facts juſt detailed ſhew, that when the nervous ſyſtem is injured above the origin of the phrenic nerves, the phenomena of death ſucceed in the following order: 1, ſuſpenſion of the action of the voluntary nerves below the injury, and conſequently of the intercoſtal and phrenic; 2, paralyſis of all the muſcles of the animal life ſupplied by thoſe nerves, particularly of the diaphragm and intercoſtal muſcles; 3, ceſſation of the mechanical phenomena of reſpiration, for want of the agents neceſſary to thoſe phenomena; 4, annihilation of the chemical phenomena. The interruption of all theſe motions is as rapid as their ſucceſſion is quick in the natural order. Death comes on in this way from a diviſion or compreſſion of the medulla ſpinalis near the brain, from a luxation of the ſecond vertebra, from concuſſion or compreſſion of the brain, &c.

Thus we ſee that reſpiration is a function of a mixed kind, placed in a manner between the two lives, and ſerving as their point of contact, belonging to the animal life by its mechanical, and to the organic by its chemical phenomena. Hence the activity of the lung depends as much on that of the brain, which is the centre of the former, as on that of the heart, which is the central organ of the latter.

LUNULARIA, in *Botany,* ſo called from the creſcent-ſhaped calyx, as it is now thought to be, of the male flowers. Mich. Gen. 4. t. 4. See *Marchantia cruciata* of Linnæus, who by miſtake cites it by the name of *Lunaria.*

LUNULATUM FOLIUM. See LEAF.

LUOPIOIS, in *Geography,* a town of Sweden, in the province of Tavaſtland; 23 miles N. of Tavaſthus.

LUPANNA, an iſland in the Adriatic, near the republic of Raguſa, which has a good and ſafe harbour. The ſoil, though ſtony, is by the induſtry of the inhabitants rendered fertile. The coaſts abound with fiſh.

LUPARA, a town of Naples, in the Moliſe; 17 miles N.E. of Moliſe.

LUPATA, a chain of African mountains in Mocaranga. S. lat. 13° to 17°.

LUPERCALIA, feaſts celebrated in Greece, and at Rome, in honour of the god Pan.

The word comes from *Lupercal,* the name of a place under the Palatine mountain, where the ſacrifices were performed.

The Lupercalia were celebrated on the fifteenth of the calends of March, that is, on the fifteenth of February; or, as Ovid obſerves, on the third day after the ides. They are ſuppoſed to have been eſtabliſhed by Evander, or brought by him from Arcadia into Italy. The Arundel Marbles aſcribe the inſtitution of theſe feaſts to Lycaon, king of Arcadia, who afterwards polluted them by ſacrificing human victims. This feaſt, after having been interrupted for ſome ages, was re-eſtabliſhed in Athens, in the time of Pandira, as we learn from the 10th era of the ſame marbles. Lycurgus aboliſhed at Lacedæmonia the barbarous cuſtom of offering human victims. Valerius Maximus is of opinion, that this feſtival was only introduced in the time of Romulus, at the perſuaſion of the ſhepherd Fauſtulus.

On the morning of the feaſt, the Luperci, or prieſts of Pan, ran naked through the ſtreets of Rome, ſtriking the married women they met on the hands and belly with a thong, or ſtrap, of goat's leather; which was held an omen promiſing them fecundity and happy deliveries.

The reaſon of this indecent cuſtom, in celebrating the Lupercalia, took its riſe, as it has been ſaid, from Romulus and Remus: for while they were aſſiſting at this feaſt, a body of robbers, taking hold of the occaſion, plundered them of their flocks. Upon this the two brothers, and all the youth that were with them, throwing off their clothes, to be the more expedite, purſued the thieves and recovered their prey. This ſucceeded ſo well, that henceforward this ceremony became a part of the Lupercalia.

This feaſt was aboliſhed in the time of Auguſtus; but it was afterwards reſtored, and continued to the time of the emperor Anaſtaſius. Baronius ſays it was aboliſhed by pope Gelaſius, in 469.

LUPERCI, a name given to the prieſts of the god Pan.

The Luperci were the moſt ancient order of prieſts in Rome; they were divided into two colleges, or companies; the one called *Fabii*, and the other *Quintilii:* to theſe Cæſar added a third, which he called *Julii*.

Suetonius mentions the inſtitution of this new college of Luperci as a thing that rendered Cæſar more odious than he was: however, it appears from the ſame paſſage of Suetonius, that this new company was not inſtituted by Cæſar, nor in honour of Pan, but by ſome friends of Cæſar, and in honour of himſelf.

LUPI Crepitus. See Crepitus.

Lupi, Didier, in *Biography*, a good harmoniſt. In the ſixteenth century he ſet to muſic the ſpiritual ſongs of Guillaume Guerret, publiſhed in 1548. He is mentioned by Rabelais in the prologue of his fourth book.

LUPIA (from λυπεω, *to moleſt*,) denotes, in *Surgery*, a tumour of the ganglion kind, or, according to Cullen, a wen.

LUPIÆ, in *Ancient Geography*, a town and colony of Italy, in Meſſapia, ſuppoſed to have been near the ſcite of the modern Leece; 24 miles S.E. of Brunduſium; but in that vicinity no veſtige of antiquity remains.

LUPINASTER, in *Botany*, Baſtard Lupine; a name given by Buxbaum and Ammann to a Siberian ſpecies of Trefoil, *Trifolium Lupinaſter* of Linnæus.

LUPINE, the common name of a ſpecies of wild pea, cultivated principally for being turned in as a manure.

This plant requires but little trouble or labour in its cultivation, as it will thrive in any ſoil, except the bad chalky, and ſuch as are very wet. It will even grow well upon poor, hungry, worn-out land, eſpecially if it be dry and ſandy. When ſown in February or March, after a ſingle very ſhallow ploughing, and ſlightly harrowed in, it will bloſſom two or three times between May and Auguſt, and prove an excellent enricher of the ground when ploughed in, juſt after its ſecond blooming. The beſt time for mowing this ſort of crop, is after a ſhower of rain, as the ſeeds drop eaſily out of the pods when they are gathered too dry. They muſt, however, be laid up very dry, or worms ſoon breed in them. They are inferior to many other plants for the above uſe.

LUPINUS, in *Botany*, ſo called by Pliny and other ancient writers. Profeſſor Martyn ſays that the word owes its origin to *lupus*, a wolf, becauſe plants of this genus ravage the ground, by over-running it, after the manner of that animal. *Lupinus* is alſo ſaid to be derived from λυπη, *grief*, whence Virgil's epithet, *triſtes lupini*, from the fanciful idea of its acrid juices when taſted producing a ſorrowful appearance in the countenance. Both theſe ideas are avowedly taken from Voſſius.—Lupine.—Linn. Gen. 371. Schreb. 492. Willd. Sp. Pl. v. 3. 1022. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 28. Loureir. Cochinch. 429. Tournef. t. 213. Juſſ. 354. Lamarck Dict. v. 3. 620. Illuſtr. t. 616. Gærtn. t. 150.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven. *Cor.* papilionaceous: ſtandard heart-ſhaped, roundiſh, emarginate, its ſides reflexed, compreſſed; wings nearly ovate, almoſt the length of the ſtandard, not affixed to the keel, joined together in the lower part; keel cloven at the baſe, falcate in the upper part, pointed, undivided, of the ſame length but narrower than the wings. *Stam.* Filaments ten, all united, ſomewhat aſcending, diſtinct above; anthers ten, five of them roundiſh, and as many oblong. *Piſt.* Germen ſuperior, awl-ſhaped, compreſſed, villoſe; ſtyle awl-ſhaped, aſcending; ſtigma terminal, obtuſe. *Peric.* Legume large, oblong, leathery, compreſſed, acuminated, of one cell. *Seeds* numerous, roundiſh, compreſſed.

Eſſ. Ch. Calyx two-lipped. Five of the anthers round, five oblong. Legume leathery, toruloſe, compreſſed.

Obſ. The calyx is ſubject to variations in different plants of this genus. Linnæus was acquainted with only ſeven ſpecies of Lupine, at leaſt he has only deſcribed that number. Lamarck has ſeventeen in his dictionary; and Willdenow gives nineteen, which he arranges in three ſections. *Sect.* 1. Herbaceous, with digitate or fingered leaves. *Sect.* 2. Shrubby, with ſimilar leaves. *Sect.* 3. Herbaceous, with ſimple leaves.

Of the firſt ſection are

L. *albus*. White Lupine. Linn. Sp. Pl. 1015. (Lupini; Matth. in Dioſc. v. 1. 392. L. ſativus; Ger. em. 1217.)—Flowers alternate. Calyx without appendages; its upper lip emarginate, the lower undivided. A native of the Levant, cultivated in various parts of Italy and the ſouth of Europe for food. The ſeeds are boiled, and afterwards ſteeped in water to extract their bitterneſs. It is common with the Romans to carry them in their pockets, eating them as they walk along in the ſtreets. The flowers appear in July, the ſeeds in autumn.—*Stem* about two feet high, branched towards the top. *Leaves* fingered, compoſed of ſeven or eight narrow, oblong leaflets, hairy, of a darkiſh grey colour, covered with a ſilvery down. *Flowers* terminal, in looſe ſpikes, white and ſeſſile. *Legumes* ſtraight, hairy, about three inches long, containing five or ſix *ſeeds*, which are roundiſh, flatted, extremely ſmooth and even, perfectly white, and unſpotted.

L. *luteus*. Yellow Lupine. Linn. Sp. Pl. 1015. Curt. Mag. t. 140.—Flowers in whorls. Calyx with appendages; its upper lip cloven, the lower three-toothed.—A native of Sicily. It flowers in July and Auguſt.—*Stem* a foot high, branching. *Leaves* fringed, compoſed of ſeven, eight, or nine hairy leaflets. *Flowers* yellow, fragrant, in whorled ſpikes. *Legumes* ovate, flattiſh, hairy. *Seeds* ovate, a little compreſſed, yellowiſh-white, variegated with dark ſpots.—This is very commonly cultivated in flower-gardens, and ſhould be ſown in the ſpring with other annuals.

The ſecond ſection conſiſts of ſeven ſpecies, all natives of the Brazils or of Peru, and deſcribed originally by Lamarck only, from whom Willdenow has adopted them.

The third ſection compriſes two fine ſpecies, *villoſus* and *integrifolius*, of which we are not acquainted with any figure; the former is a native of Carolina, the latter of the Cape.—Loureiro deſcribes two others of this ſection, *L. cochinchinenſis* and *africanus*, but from the latter having its leaves ternate, like thoſe of *L. trifoliatus*, Cavan. Ic. v. 8. t. 59, we are inclined to think it ſhould be referred to ſome other genus.

Lupinus, in *Gardening*, contains plants of the hardy, herbaceous, annual, and perennial flowery kinds; of which the ſorts moſtly cultivated are, the white lupine (L. albus); the ſmall blue lupine (L. varius); the narrow-leaved blue lupine (L. anguſtifolius); the great blue lupine (L. hirſutus); the yellow lupine (L. luteus); and the perennial lupine (L. perennis).

In the fourth ſort there is a variety which has fleſh-coloured flowers, and which is uſually denominated the *roſe* lupine.

Method of Culture.—Theſe well-known flowering plants may be readily raiſed by ſowing the ſeeds in patches in the borders, with other annuals in the ſpring, where they are to remain;

remain ; thinning them afterwards where they are too cloſe, and keeping them clean from weeds. In order to have a ſucceſſion of flowers, the ſeed ſhould be ſown at different times, as in April, May, and June. The ſeed of thoſe only which are firſt ſown, however, ripens well. And in order to have good ſeed of the fourth kind, ſome ſeeds ſhould be ſown in a ſunny border under a wall, or in pots placed under frames, the plants in the latter caſe being turned out and planted with balls of earth about them in the ſpring. The laſt ſort ſhould be ſown at different times.

Theſe are all uſeful plants for producing variety in the borders, clumps, and other parts of pleaſure grounds and gardens.

LUPO, in *Geography*, a town of Hinder Pomerania, on a river of the ſame name ; 15 miles E. of Stolpe.

LUPOGLAVO, a town of Iſtria ; 22 miles S.E. of Trieſte.

LUPPURG, a town of Bavaria, in the principality of Neuburg ; 16 miles N.W. of Ratiſbon.

LUPULUS, in *Botany*, the diminutive of *lupus*, a wolf, a name applied by the older botaniſts to the Hop, (ſee HUMULUS,) becauſe, as the wolf preys upon other animals, ſo this plant, by immoderately impoveriſhing the ſoil in which it grows, ſtarves its vegetable neighbours. Such at leaſt is the explanation of Ambroſinus.

LUPUS, WOLF, in *Aſtronomy*, a ſouthern conſtellation joined to the Centaur, whoſe ſtars in Ptolemy's Catalogue are nineteen ; in the Britannic Catalogue, with Sharp's Appendix, twenty-four. See CENTAUR, and CONSTELLATION.

LUPUS SERVATUS, in *Biography*, a French abbot, celebrated for his learning, eloquence, and piety, deſcended from a conſiderable family in the dioceſe of Sens, was born about the commencement of the ninth century. He had from early youth a decided turn for theological purſuits, and in 828 he went to the abbey Fulda in Germany, where he ſtudied the ſcriptures under the celebrated Rabanus, who, at his requeſt, compoſed his "Commentaries upon the Epiſtles of St. Paul." He obtained conſiderable church preferment by the patronage of Lewis le Debonnaire, and Charles the Bald ; and by the latter he was ſent ambaſſador to pope Leo IV., and he was appointed, in conjunction with the celebrated Prudentius, to reform all the monaſteries in France. The time of his death is unknown, but it is aſcertained that he was living in 861. He was a conſiderable theological writer : and he publiſhed accounts of the lives of St. Wigbert, and of St. Maximin. A collection has been made of 130 of his "Letters" upon different ſubjects relating to difficulties in grammar, civil and eccleſiaſtical affairs, points of doctrine, diſcipline, and good morals, which are written with elegance, and throw much light on the hiſtory of the period in which he lived. Moreri.

LUPUS, CHRISTIAN, a learned Flemiſh monk of the order of St. Auguſtine, was born at Ypres in 1612, and embraced a religious life at the early age of fifteen. He completed his maturer ſtudies at Cologne, and was afterwards ſent to Louvain to teach philoſophy ; in which he acquired ſuch celebrity, as to ſecure the particular eſteem of the learned Fabio Chigi, then the papal nuncio in Germany, afterwards known as pope Alexander VII. In 1655, Lupus was one of the deputies ſent to Rome by the univerſity of Louvain, to negociate ſome matters of importance with the papal court, which he executed to the ſatisfaction of his employers. On his return he was appointed profeſſor of divinity at Louvain, the duties of which he performed with great ſucceſs. After this he filled the principal poſts belonging to his order in that province. Pope Clement IX. would willingly have made him a biſhop ; and from Innocent XI. and the grand duke of Tuſcany, he received repeated marks of eſteem ; the latter was deſirous of ſettling upon him a conſiderable penſion, that he might attach him to his court. He died in 1681, at the age of ſeventy. He left behind him many valuable works, of which the chief are "Commentaries on the Hiſtory and on the Canons of Councils, both general and particular," in five volumes 4to. ; "A Collection of Letters and Monuments, relating to the Councils of Epheſus and Chalcedon ;" "A Collection of the Letters of St. Thomas of Canterbury, with a Life prefixed ;" "A Commentary on the Reſcriptions of Tertullian." Moreri.

LUPUS, in *Ornithology*, a name given by ſome authors to the *monedula*, or jackdaw, from his voracious appetite and habit of ſtealing. See CORVUS *Monedula*.

LUPUS, in *Surgery*, the diſeaſe frequently called *noli me tangere*.

LUPUS, in *Zoology*, a ſpecies of *Canis*. See WOLF.

LUPUS *Aureus*, the *gold-coloured wolf*, the name by which Latin authors call the creature known in Engliſh by the name of the *jackal*. See AUREUS.

LUPUS *Cervarius*, a name by which many authors have called the *lynx*, from its feeding on deer. See FELIS *Lynx*.

LUPUS *Marinus*, a name given by Jonſton, Bellonius, and Geſner, to the *Canis hyæna*. See HYÆNA.

LUPUS *Marinus*, the *Sea-wolf*, the *Anarhicas lupus* of Linnæus, in *Ichthyology*, a fierce and voracious ſea-fiſh, confined to the northern ſeas of our globe. It is found in thoſe of Greenland, Iceland, and Norway, on the coaſts of Scotland and of Yorkſhire, and in that part of the German ocean which waſhes the ſhores of Holland. Its head is larger in proportion to its ſize than that of the ſhark, and rounder, a little flatted on the top ; the noſe blunt ; the noſtrils very ſmall ; the eyes ſmall, and placed near the end of the noſe ; the body is long, and a little compreſſed ſideways ; the back, ſides, and fins, are all of a livid lead colour ; the two firſt marked downwards with irregular, obſcure, duſky lines, which in different fiſh have different appearances. The young are of a greeniſh caſt ; the belly is white ; the ſkin is ſmooth and ſoft, but his teeth ſo remarkably hard and ſtrong, that if he bites againſt an anchor of a ſhip, or other iron ſubſtance, he makes a loud noiſe, and leaves his marks in the iron ; the fore-teeth are ſtrong, conical, diverging a little from each other, ſtand far out of the jaws, and are commonly ſix above and ſix below, though ſometimes there are only five in each jaw ; theſe are ſupported withinſide by a row of leſſer teeth, which make the number in the upper jaw ſeventeen or eighteen, and in the lower eleven or twelve. The ſides of the lower jaw are convex inwards, and the grinding teeth of this jaw are higher on the outer than the inner edges, and join to the canine teeth, but in the upper are ſeparated from them ; in the centre are two rows of flat ſtrong teeth, fixed on an oblong baſis upon the bones of the palate and noſe ; theſe and the other grinding teeth are often found foſſil, and called *bufonites*, or toad-ſtones. The two bones that form the under jaw are united before by a looſe cartilage, ſerving by a free motion to the purpoſe of breaking, grinding, and comminuting its teſtaceous and cruſtaceous food, as crabs, lobſters, prawns, muſcles, &c. At the entrance of the gullet, above and below, are two very ſmall echinated bones. It has two fins, like wings, ſituated juſt under the gills ; and one long dorſal fin running from the head to the tail, and another reaching from the anus to the tail; the tail is round at its end, and conſiſts of thirteen rays. This fiſh grows to a large ſize, being ſometimes found on the Yorkſhire coaſt of the length of four feet, and near Shetland more than ſeven feet. Pennant.

LURA, in *Geography*, a town of South America, in the province of St. Martha, on the Madalena; 8 miles S. of Teneriffe.

LURBAH, a town of Bengal; 20 miles S.S.W. of Doeſa. N. lat. 22° 41′. E. long. 85°.

LURCH, To, in *Fencing*, is to make an opening in order to invite your adverſary to thruſt at you, when you, being ready, may find a favourable repoſt at him.

LURCHER, among *Sportſmen*, a kind of hunting dog, like a mongrel greyhound, with pricked ears, a ſhaggy coat, and generally of a yellowiſh-white colour. See Dog.

LURCY-le-Sauvage, in *Geography*, a town of France, in the department of the Allier, and chief place of a canton, in the diſtrict of Moulins; 7 miles E.N.E. of Donjon. The place contains 2461, and the canton 8548 inhabitants, on a territory of 265 kiliometres, in 12 communes.

LURE, in *Falconry*, a piece of red leather cut in form of a bird, with two wings ſtuck with feathers; and ſometimes baited with a piece of fleſh: wherewith to reclaim, or call back a hawk.

The word comes from the French *leurre*, which ſignifies the ſame: formed, according to Skinner, from the Anglo-Saxon, *læura*, *traitor;* or, according to Tripaud, from *leora*, *craſtineſs*. See Falcon and Hawking.

Lure, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Upper Saône, near the Ougnon. The place contains 1918, and the canton 12,339 inhabitants, on a territory of 227½ kiliometres, in 25 communes. N. lat. 47° 41′. E. long. 6° 34′.

LURGAN, a market and poſt-town of the county of Armagh, Ireland; it is in the north-eaſtern angle of the county, near Down, and conſiſts of one long wide ſtreet, remarkable for cleanlineſs. Its trade conſiſts in articles of the linen and muſlin manufactures, of which the weekly ſales are averaged from 2500*l.* to 3000*l.* Fine diapers for table linen manufactured in this town have been highly valued. Lurgan is 68 miles N. from Dublin.

Lurgan, a townſhip of America, in Franklin county, Pennſylvania, containing 758 inhabitants.

Lurgan *Green*, a ſmall poſt-town of the county of Louth, Ireland, pleaſantly ſituated on Dundalk-bay. It is on the great northern road, 37 miles N. from Dublin.

LURIDÆ, in *Botany*, from *luridus*, pale, livid, or ghaſtly, alluding to the livid and blueiſh aſpect, frequent in the tribe of plants thus denominated, which ſeems to announce their deadly effects on animal life. They conſtitute the 28th natural order, among the *Fragmenta* of Linnæus, and are exemplified by *Digitalis, Nicotiana, Atropa, Hyoſcyamus, Datura, Phyſalis, Capſicum, Solanum, Verbaſcum, Celſia, Lycium, Ceſtrum;* to which *Triguera* of Cavanilles, as well as *Witheringia* of l'Heritier, are properly added by Giſeke. But *Browallia, Elliſia, Strychnos, Ignatia,* and above all *Cateſbæa*, are with leſs reaſon referred hither by Linnæus.

The true *luridæ* have commonly a fetid herbage, though ſometimes a ſweet-ſmelling flower. They act powerfully upon the nerves, in whatever manner they are taken inwardly, and prove, under careful management, in ſome caſes, very valuable medicines, though naturally violent poiſons.

LURIGANCHE, in *Geography*, a town of Peru, in the juriſdiction of Lima.

LURIN, a town of Peru, in the juriſdiction of Lima.

LURKIAN, a town of Perſia, in the province of Chuſiſtan; 50 miles N. of Suſter.

LURY, a town of France, in the department of the Cher, and chief place of a canton, in the diſtrict of Bourges, ſituated on the Arnon; 13 miles W. of Bourges. The place contains 512, and the canton 4575 inhabitants, on a territory of 170 kiliometres, in 9 communes.—Alſo, a town of the iſland of Corſica; 13 miles N. of Baſtia.

LUS, St., a town of Mexico, in the province of Guatimala; 12 miles E. of Guatimala.

LUSATIA, a marquiſate of Saxony, bounded on the N. by the Mark of Brandenburg, on the E. by Sileſia, on the S. by Bohemia, and on the W. by Saxony; about 84 miles long, and 45 broad, divided into Upper and Lower Luſatia. The former abounds in mountains and hills, and enjoys a purer air than the latter, which is covered with a great number of woods. Peat and turf are found in different parts. Upper Luſatia is ill adapted to agriculture, but affords plenty of game. Lower Luſatia has heaths and fertile tracts. In both rye, wheat, barley, and oats are cultivated, together with buck wheat, peaſe, lintels, beans, and millet. Flax is alſo cultivated. As to orchard and garden fruits, and the culture of hops, tobacco, and wine, Lower Luſatia is preferable to the Upper. Neverthele ſs, the products of the country are not adequate to its conſumption, ſo that corn, fruit, hops, garden ſtuff, and wine, are imported into both theſe marquiſates. Cattle are bred in conſiderable number, and the rivers, lakes, and ponds afford various ſorts of good fiſh. In ſome parts are found pipemaker's clay, and ſtone quarries. Stones reſembling the Bohemian diamonds, agates, and jaſpers, and iron ſtone, are met with in ſeveral places: and here is a variety of medicinal ſprings. The chief rivers are the Spree, the Black Elſter, and the Pulſnitz. In Upper Luſatia are reckoned ſix towns, called "The Six Towns," 16 ſmaller towns, and four market towns; and in the Lower four towns, which appear at the land diets, 13 county towns, and two market ones. The firſt known inhabitants of this country were the Semnones, or Senones, who were ſucceeded by the Wandalers, and theſe again in the 7th century by a Sclavonian people, called the Sorber-Wends. In the 12th century the inhabitants of this country were intermixed by emigrants from the Low Countries and the Rhine. Some of the towns are now wholly peopled by Germans, but in the villages the Wends are more numerous than the Germans. Lutheraniſm was introduced into this country as early as the year 1521; it generally prevailed, and has been the permanent religion of the country. In 1750, the Hernhuters obtained protection as faithful ſubjects, and in conſequence of purchaſing ſeveral conſiderable eſtates, they have not only acquired civil power, but the patronage of churches. The inhabitants of Luſatia gain their ſubſiſtence by the manufacture of numerous woollen and linen ſtuffs; which moſtly flouriſh in Upper Luſatia. The manufactures of Luſatia have been promoted by the emigration of the Proteſtants, who were driven thither from Bohemia and Sileſia by the conduct of the emperors Ferdinand II. and III. and alſo of Leopold: and thus they have been extended, beyond cloth and linens of various ſorts, to thoſe of hats, leather, paper, gunpowder, iron, wax, glaſs, and wax-bleaching, and a variety of handicraft arts and operations. By theſe manufactures they have been enabled to carry on a trade, ſo that the commodities they diſpoſe of exceed thoſe which they import, which are wool, yarn, and ſilk, corn, fruit, hops, &c. The whole of Luſatia, except a ſmall part which is ſubject to Pruſſia, belongs to Saxony, having been ceded to the elector about the middle of the 16th century, in conſideration of a large ſum of money advanced by the elector to the emperor, in his war with the Bohemians.

LUSCHETZ, a town of Bohemia, in the circle of Schlan; 8 miles S.W. of Prague.

LUSCINIA, in *Ornithology*, a ſpecies of *Motacilla*, which ſee. See alſo NIGHTINGALE.—Alſo, a ſpecies of Certhia. See CERTHIA *Flaveola*.

LUSCINIOLA, the *Bogeuch* of Pennant, and *red warbler* of Latham. See MOTACILLA *Schœnobenus*.

LUSCINIUS, OTTOMARUS, in *Biography*, a Benedictine monk, born at Straſburg, but an inhabitant of Augſburg, publiſhed in 1536 a work, entitled "Muſurgia ſeu praxis Muſicæ," in ſmall oblong quarto; a book chiefly curious and valuable for the repreſentations of ſuch muſical inſtruments as were uſed in Germany at the time it was written, which, though coarſely cut in wood, are accurately drawn. There are, among keyed-inſtruments, the virginal, ſpinnet, and clavichord, all three in the form of a ſmall modern piano-forte; an upright harpſichord; a regal or portable organ, chiefly compoſed of reed-ſtops, and in Roman Catholic countries uſed in proceſſions; and a large or church-organ. Of bowed-inſtruments we have here only the monochord, rebec, or three-ſtringed violin, and the viol da gamba. The vielle, lute, harp, and dulcimer; cornet, ſchalmey, or baſe clarinet, both played with reeds; flutes of various ſize, among which is the Zwerchpfeiff, flute traverſiere, or, as we call it, the German flute; which accounts for its name, as we believe, at this early period, it was unknown to the reſt of Europe. There are four other wind-inſtruments, peculiar to Germany and northern countries, exhibited here: as, firſt, the ruſpfeiff, or Ruſſian flute; ſecond, the krumhorn, or crooked horn, a kind of ſhawm, in imitation of which we have a reed-ſtop in our old organs, called the cromhorn, which has by ſome been imagined to be a corruption of the word Cremona; third, gemſen horn, or wild goat's horn; and, fourth, the zincke, or ſmall cornet. After theſe we have the bag-pipe, trumpet, ſacbut, ſide-drum, kettle-drum, French-horn, bugle-horn, and even the Jews-harp, and clappers. Moſt of theſe inſtruments being in common uſe, and well known, need no repreſentation after the rude types of them given by Luſcinius, as they have been ſince much better delineated and engraved in Merſennus, Kircher, and in ſtill later muſical writers.

LUSEPARA, in *Geography*, an iſland that lies in the ſouth entrance of the ſtraits of Banca. S. lat. 3° 10′ 30″. E. long. 106° 15′.

LUSHBURGHS, or LUXENBURGHS, in our *Old Writers*, a baſe ſort of foreign coin, made of the likeneſs of Engliſh money, and brought into England in the time of Edward III. to deceive the king and his people: on account of which it was made treaſon, for any one willingly to bring any ſuch money into the realm, as knowing it to be falſe. Stat. 23 Edw. III. 3 Inſt. 1.

LUSIAD *of Camoens*. See CAMOENS.

LUSIGNAN, in *Geography*, a town of France, in the department of the Vienne, and chief place of a canton, in the diſtrict of Poitiers. The place contains 2390, and the canton 13,147 inhabitants, on a territory of 342½ kiliometres, in 10 communes. N. lat. 46° 26′. E. long. 0° 14′.

LUSIGNY, a town of France, in the department of the Aube, and chief place of a canton, in the diſtrict of Troyes. The place contains 1155, and the canton 7225 inhabitants, on a territory of 180 kiliometres, in 14 communes.

LUSITANIA, in *Ancient Geography*, one of the two provinces into which Hiſpania Ulterior was divided; the other being Bœtica. (See HISPANIA.) Its limits have been variouſly defined by different authors, and particularly by Pliny and Ptolemy. Strabo intimates, that this province extended from the Tagus to the Cantabrian ocean, or at leaſt the Promontorium Celticum. That part of it, ſituated betwixt the Anas and the Tagus, was denominated Celtica, or the country of the Celts. After Auguſtus made the diſpoſition of Spain, referred to under the article *Hiſpania*, the Anas bounded Luſitania on the ſouth, and the Durius on the north; ſo that the whole tract lying betwixt the Durius and the Cantabrian ocean was annexed to the Provincia Tarraconenſis. The interior limits of Luſitania, upon the frontiers of the Vettones and Carpetani, are differently fixed by different authors. The Luſitani poſſeſſed the diſtrict bordering upon the Atlantic ocean, and ſtretching itſelf from the mouth of the Anas to the Promontorium Sacrum, now known by the name of Cape St. Vincent. The ſituation of the Celtici, whoſe true name was Mirobrigenſes, according to Pliny, may be inferred from the preceding part of this article. Some of the ancient geographers make the Turduli and the Turdetani one nation, particularly Ptolemy and Strabo; though they were conſidered in a different light by Polybius. However this be, the Turdetani were undoubtedly a powerful people, ſince they occupied a conſiderable part both of Luſitania and Bœtica, as we learn from Strabo. The ſame may be ſaid of the Vettones, who ſpread themſelves over a large tract, terminated on the north by the Durius, and on the ſouth by the Tagus. Nevertheleſs, as the ancients differ with regard to the extent of territory every one of thoſe nations or cantons poſſeſſed, it is probable that their frontiers were not always the ſame. Some authors aſſert Vettonia, or the country of the Vettones, to have been a province diſtinct from Luſitania, and limited on the ſouth by the Anas; and this notion is countenanced by an inſcription in Gruter. The principal cities of this province are Barbarium Promontorium, Oliſippo, Tagi Fluvii Oſtia, Fortes Fluv., Lunæ Montis Promontorium, Mondæ Fluv. Oſtia, Vaci Fluv. Oſtia, Doriæ Fluv. Oſtia, Hannibal. Inland towns were Lavara, Aritium, Salium, Elbocoris, Araducta, Verarium, Velladis Æminium, Chretina, Arabriga, Scalabiſcus, Tacubis, Concordia, Talabriga, Langobriga, Mendeculia, Caurium, Turmogum, Burdua, Colernum, Iſallæcus, Ammæa, Ebura or Ebora, Norba Cæſarea, Liciniana, Auguſta Emerita, which was the capital, Evandria, Geræa, Cæcilia Gemittina, Capaſa, Conimbrica, Collipo, Bletiſa, Salmantica, Salatia, Pax Julia, and ſome others of leſs note. The chief promontories of Luſitania were the Promontorium Sacrum, or Cape St. Vincent; P. Barbarium, or Cape Spichel; and the P. Magnum, or Oliſiponenſe, denominated by ſome moderns Cape de Rocca Sintra; to which ſome add a fourth, called by Pliny Cuneus or the Wedge, ſuppoſed to be now known by the name of Cape St. Mary. The principal ports of this province were thoſe of Oliſippo or Liſbon, and Hannibal. The only iſland on the coaſt of Luſitania was the Londobris of Ptolemy, the Barlenga or Barlinges of the moderns. The only mountain of note in this country was the Mons Herminius of Hirtius, or the modern Arminno, ſince known by the name of Sierra de Eſtretta, running from north to ſouth, between the provinces of Beira and Tra los Montes. On the top are two extenſive and deep lakes, calm when the ſea is ſo, and rough when that is ſtormy. Theſe lakes are ſuppoſed to have ſome ſubterranean communication with the ocean. Herminius Minor is now Sierra de Marvao. The warlike inhabitants of the former were called Plumbarii, from their lead-mines and works. The moſt celebrated rivers of Luſitania were the Anas, now Guadiana, the Tagus or Tajo, and the Durius or Douro; to which may be added the Munda or Mondago, and the Vacus or Voga: all theſe flow from eaſt to weſt, and diſcharge themſelves into the Atlantic ocean. This province produced a conſiderable quantity of gold, particles of it being mixed with the ſand of the Tagus. The lead-mine of Medobriga or Meidobriga, at the foot of Herminius Minor, was famous.

The Luſitanians, according to Strabo, preferred exiſting upon the plunder of their neighbours to the improvement of their own lands, though the ſoil was naturally fertile and rich. In other caſes their manner of living was rude and ſimple. They uſed to warm themſelves by means of fire-ſtones made red-hot. They bathed in cold water, eat only of one diſh at a meal, and very ſparingly. Their dreſs was commonly black. They made no uſe of coin, but either bartered one commodity for another, or for ſome plates of ſilver, flatted with the hammer, and cut into pieces. They uſed, like the Egyptians, Gauls, and other ancient nations, to expoſe their ſick on the highways, that travellers might direct them to proper medicines for their cure. They were exceedingly robuſt, and ſo warlike that the Romans did not conquer them without great difficulty and length of time. See PORTUGAL.

LUSITANICA *Rubra Bolus*, is an impure earth, of a florid red colour, compact texture, and heavy: it colours the hands, and is very friable, readily diſſoluble in water, and raiſes with it a ſtrong ebullition; it melts readily in the mouth, has a ſtrong aſtringent taſte, is gritty, and adheres firmly to the tongue. It acquires hardneſs and a brighter colour by burning; it is of an alkaline quality; it is dug in the kingdoms of Portugal and Spain; it is alſo found near the Havannah and La Vera Cruz in New Spain. It has been eſteemed a very valuable aſtringent, and an effectual remedy for fluxes and other diſtempers of that kind. It has been alſo accounted alexipharmic by the Spaniards and Portugueſe. They make an earthen ware of this bole, which they call bucaros: the ware is of a fine red colour, ſmooth, and poliſhed, though it is merely dried, and not glazed. They uſe it to filtre, cleanſe, and cool the water. Veſſels of the ſame kind are alſo brought from the Havannah and Vera Cruz.

LUSK, in *Geography*, a fair-town in the county of Dublin. Ireland. According to Archdell, an abbey was founded here in the firſt ages of Chriſtianity; and there is adjoining the angle of the ſteeple of the church, one of thoſe ancient round towers ſo peculiar to Ireland: it is in good preſervation, and riſes ſeveral feet above the battlements of the ſteeple. It is 11 miles N. by E. from Dublin.

LUSPA, a town of Sweden, in Eaſt Bothnia; 28 miles E. of Chriſtineſtadt.

LUSSAC, a town of France, in the department of the Gironde, and chief place of a canton, in the diſtrict of Libourne; 6 miles E.N.E. of Libourne. The place contains 2032, and the canton 9072 inhabitants, on a territory of 157½ kiliometres, in 16 communes.—Alſo, a town of France, in the department of the Vienne, and chief place of a canton, in the diſtrict of Montmorillon; 6 miles W. of Montmorillon. The place contains 1379, and the canton 9470 inhabitants, on a territory of 400 kiliometres, in 13 communes.

LUSSAN, MARGARET DE, in *Biography*, was born at Paris in 1682. Her parents were in the lower rank of life; the mother being a fortune-teller, and the father a coachman. She, by ſome means, attracted the notice of the learned Huet, who, ſtruck with the vivacity of her temper, encouraged her to write romances. She derived great advantage in the formation of her taſte, from her connection with la Serre de Langlade, to whom ſhe was much attached; but the love was not mutual: her charms were wholly mental; her perſon and manners were even forbidding; but ſhe was generous, humane, and conſtant in her friendſhips. She died at the age of 75. Her works are "L'Hiſtoire de la Comteſſe de Gondès," "Anecdotes de la Cour de Philippe Auguſte," "Memoires Secrets et Intrigues de la Cour de France ſous Charles VIII.," "Marie d'Angleterre," "Annales de la Cour de Henri II.," "La Vie du brave Crillon."

LUSSAN, in *Geography*, a town of France, in the department of the Gard, and chief place of a canton, in the diſtrict of Uzès; nine miles N. of Uzès. The place contains 997, and the canton 5493 inhabitants, on a territory of 239 kiliometres, in 13 communes.

LUSSEMEN, a town of Pruſſia, in the province of Ermeland; 18 miles E.S.E. of Heilſberg.

LUST, at *Sea*. If a ſhip heel either to the ſtar-board or port, the ſeamen ſay ſhe hath a *luſt* that way; and they ſay ſo though it be occaſioned only by the ſhooting of her ballaſt, or by the unequal ſtowing of things in the hold; though it is more properly ſaid of a ſhip, when ſhe is inclined to heel any way upon account of her mould or make.

LUST-*wort*, in *Botany*. See SUN-*dew*.

LUSTER, or LUSTRE, gloſs, or brightneſs appearing on any thing; particularly on manufactures of ſilk, wool, or ſtuff.

LUSTER is alſo uſed for a certain compoſition, or manner of giving that gloſs or brilliance.

The luſtre of ſilks, in which their chief beauty conſiſts, is given them by waſhing in ſoap, then clear water, and dipping them in alum-water cold.

The luſtre of black taffety is given by double-brewed beer, boiled with orange or lemon-juice; that of coloured taffetas with water of gourds, diſtilled in an alembic. Curriers give a luſtre, or gloſs to the leather ſeveral ways, according to the colour to be illuſtrated. For blacks, the firſt luſtre is with juice of barberries; the ſecond with gum arabic, ale, vinegar, and Flanders glue, boiled together: for coloured leathers they uſe the white of an egg beaten in water: moroccos have their luſtre from juice of barberries, and lemon or orange.

For hats, the luſtre is frequently given with common water; ſometimes a little black dye is added. The ſame luſtre ſerves ſkinners, except that in white furs they never uſe any black dye. For very black furs they ſometimes prepare a luſtre of galls, copperas, Roman alum, ox's marrow, and other ingredients.

The luſtre is given to cloths and mohairs, by preſſing them under the calender.

LUSTER, an appellation given to a branched candleſtick, when made of glaſs. See BRANCH and JESSE.

LUSTIG, JACOB WILHELM, in *Biography*, organiſt of St. Martin's church in Groningen, publiſhed, in 1771, in the Dutch language, "An Introduction to the Art of Muſic, 2d edition, corrected and enlarged," 8vo. This introduction is better digeſted, and more abundant in uſeful information, than the generality of elementary treatiſes. The author had read, meditated, and ſtudied muſic regularly, both in theory and practice; and was a good compoſer of the old ſchool. He had been a diſciple both of Mattheſon and Telemann. We have ſeen a book of leſſons of his compoſition, which has great merit. In this book we found the croſs-hand jig, in $\frac{12}{8}$, which the little Frederica, afterwards Mrs. Wynne, and other infant performers, uſed to play at the end of a minuet of Tartini with variations by Paradies, generally known by the name of Paradies' minuet. In 1772 we had the pleaſure of converſing with this worthy profeſſor (Luſtig), and of hearing him play on the organ of St. Martin's church in Groningen, of which he had been organiſt 44 years; ſtill retaining his hand, and, a few allowances made for change of taſte and ſtyle, he was ſtill a very able and good organiſt.

LUSTRAL, an epithet given by the ancients, to the water uſed in their ceremonies, to ſprinkle and purify the people. From hence the Romaniſts have borrowed the holy water uſed in their churches.

Lustral *day*, *dies Luſtricus*, that whereon the luſtrations were performed for a child, and its name given; which was uſually the ninth day from the birth of a boy, and the eighth from that of a girl. Though others performed the ceremony on the laſt day of that week wherein the child was born, and others on the fifth day from its birth.

Over this feaſt day the goddeſs Nundina was ſuppoſed to preſide; the midwives, nurſes, and domeſtics, handed the child backwards and forwards, around a fire burning on the altars of the gods, after which they ſprinkled it with water; hence this feaſt had the name of Amphidromia. The old women mixed ſaliva and duſt with the water. The whole ended with a ſumptuous entertainment. The parents received gifts from their friends on this occaſion. If this child was a male, their door was decked with an olive-garland: if a female with wool, denoting the work about which they were to be employed. Potter.

LUSTRATION, Expiation, in *Antiquity*, ſacrifices or ceremonies, by which the Romans purified their cities, fields, armies, or people defiled by any crime, or impurity. Some of the luſtrations were public, others private.

There were three ſpecies, or manners of performing luſtration; *viz.* by fire and ſulphur; by water; and by air; which laſt was done by fanning and agitating the air round the thing to be purified.

There was alſo a peculiar kind of luſtration for young children.

Lomier has a volume expreſs on the luſtrations of the ancients: Joh. Lomieri Zutphanenſis Epimenedes, ſive de veterum Gentilium Luſtrationibus; firſt printed at Utrecht in 1681, and ſince, with additions, in 1702, 4to.

All perſons, ſlaves only excepted, he ſhews, were miniſters of ſome ſorts of luſtration. When any one died, the houſe was to be ſwept after a particular manner, by way of purification; the prieſt threw water on new married people, with the like intention. To purify themſelves, people would even ſometimes run naked through the ſtreets; ſuch was their extravagance. And, as if fancy was not fertile enough in inventing modes of luſtration, they even uſed inchantments to raiſe the dead, in order to get inſtructions what they muſt do to purge themſelves of their ſins. Add, that they frequently raiſed the opinion of the ſanctity of their expiations by fictitious miracles.

It was common, on theſe occaſions, to ſhed human blood: the prieſts of Cybele, Bellona, and Baal, made cruel inciſions on themſelves. Erectheus, king of Attica, ſacrificed his daughter to Proſerpina. Several had their throats cut at Rome, to obtain the emperor's health from the gods. Thoſe who commanded armies offered one of their ſoldiers to appeaſe the anger of the gods; that he alone might ſuffer all the wrath the army deſerved.

All ſorts of perfumes, and odoriferous herbs, had place in luſtration. The egg was much uſed among them, as being the ſymbol of the four elements; its ſhells, they ſay, repreſent the earth; the yolk, a globe of fire; the white, reſembles the water; and beſides it has a ſpirit, they ſay, which repreſents the air. For this reaſon it is, that the bonzes, or Indian prieſts, believe to this day that the world came out of an egg. There is ſcarce any pot-herb, pulſe, tree, mineral, or metal, which they did not offer the gods by way of expiation: nor did they forget milk, bread, wine, or honey; what is more, they made uſe of the very ſpittle, and urine.

The poets had feigned, that the gods purified themſelves, and they did not omit to purify their ſtatues. They made luſtration for children the eighth day after their birth. When a man who had been falſely reputed dead, returned home, he was not to enter his houſe by the door. It was a ſettled cuſtom to offer no expiation for thoſe who were hanged by order of juſtice; or that were killed by thunder. Neither did they offer any for thoſe who were drowned in the ſea; it being the common opinion, that their ſouls periſhed with their bodies. And hence it was, that perſons in danger of ſhipwreck, ſometimes thruſt their ſwords through their bodies, that they might not die in the ſea; where they thought their ſoul, which they ſuppoſed to be a flame, would be totally extinguiſhed. The moſt celebrated expiatory ſacrifice was the hecatomb, when they offered a hundred beaſts; though they commonly did not offer ſo many, but contented themſelves with killing twenty-five; but thoſe being quadrupeds, their feet came to an hundred.

The manner of the Macedonians purifying their army by luſtration was this; at the time of their feſtival Xanthica, they divided a bitch into two halves, one of which, together with the entrails, was placed upon the right hand, the other upon the left; between theſe the army marched in this order: after the arms of the Macedonian kings, came the firſt line of the army, conſiſting of horſe; theſe were followed by the king, and his children, after whom went the life guards; then followed the reſt of the army: this done, the army was divided into two parts, one of which being ſet in array againſt the other, there followed a ſhort encounter in imitation of a fight. Potter, Archæol. Græc. lib. ii. c. 20. tom. i. p. 417.

Luſtrations, and luſtratory ſacrifices, were not only performed for men, but alſo for temples, altars, theatres, trees, fountains, rivers, ſheep, fields, and villages. When the Arval brothers offered a victim for the fields, their ſacrifice was called *ambarvalia*.

Cities were alſo to be purified, from time to time: ſome made the victim walk round their walls, and then ſlew him. The Athenians ſacrificed two men, one for the men of their city, and the other for the women. The Corinthians ſacrificed the children of Medea ſo: though the poets ſay, Medea killed them herſelf. The Romans performed the ceremony of purifying their city every fifth year; whence the name of luſtrum was given to the ſpace of five years.

Divers of the expiations were auſtere: ſome faſted; others abſtained from all ſenſual pleaſures; ſome, as the prieſts of Cybele, caſtrated themſelves; others, that they might live chaſte, eat rue, or lay under the branches of a ſhrub called *agnus caſtus*.

They caſt into the river, or at leaſt out of the city, the animals or other things that had ſerved for a luſtration, or ſacrifice of atonement; and thought themſelves threatened with ſome great misfortune, when by chance they trod upon them. At Marſeilles, they took care to feed a poor man for ſome time; after which, they charged him with all the ſins of the country, and drove him away: thoſe of Leucade faſtened a number of birds to a man charged with their ſins, and in that condition caſt him headlong from a high tower; and if the birds hindered his being killed, they drove him out of the country.

Some of theſe ceremonies were aboliſhed by the emperor Conſtantine, and his ſucceſſors; the reſt ſubſiſted till the Gothic kings were maſters of Rome, under whom they expired; except that ſeveral of them were adopted by the popes, and brought into the church, where they make a figure to this day: witneſs the numerous conſecrations, benedictions, exorciſms, ablutions, ſprinklings, proceſſions, feaſts, &c. ſtill in uſe in the Roman church.

LUSTRINGS. A company was incorporated for making, dreſſing, and luſtrating alamodes and luſtrings in England, who were to have the ſole benefit thereof, by ſtat. 4 and 5 W. and M. And no foreign ſilks known by the name of luſtrings or alamodes are to be imported, but at the port of London, &c. Stat. 9 and 10 W. III. c. 43. See Silk.

LUSTRUM, a term uſed by the Romans, to ſignify a ſpace of five years.

Varro derives the word from *luo, to pay*; becauſe at the beginning of every fifth year they paid the cenſus, or tribute impoſed by the cenſors; whoſe authority, at their firſt inſtitution, was continued them for five years; though afterwards it was abridged to one. Others rather derive the word from *luſtrare, to make a review*; becauſe once in five years the cenſors reviewed the army.

Lustrum was alſo a ceremony, or ſacrifice uſed by the Romans, after numbering their people, once in five years. See Lustration.

The cenſus was accompanied always by a luſtration of the people, ſo the word luſtrum has conſtantly been taken by the ancients and moderns for a term of five years: yet if we enquire into the real ſtate of the caſe, we ſhall find no good ground for fixing ſo preciſe a ſignification to it; but, on the contrary, that the cenſus and luſtrum were, for the moſt part, held irregularly and uncertainly, at very different and various intervals of time, as the particular exigencies of the ſtate required. Middlet. of Rom. Sen. p. 107.

LUTANGER, in *Geography*, a ſmall iſland in the Eaſt India ſea, near the S. coaſt of Mindanao. N. lat. 7° 19′. E. long. 123° 15′.

LUTATION, in *Chemiſtry*, is uſed for the cementing of chemical veſſels cloſe together.

LUTAYA, in *Geography*, one of the ſmaller Philippine iſlands, near the iſland of Panay.

LUTE, Lutum, in *Chemiſtry*, a compoſition of certain tenacious ſubſtances, wherewith to cloſe the apertures and junctures of veſſels in diſtillation, &c. See Cæment, Cement, and Mortar.

Lute, *Leuto*, Ital., *Laute*, Germ., a muſical ſtringed inſtrument, of which, though the ſhape or ſound is now hardly known, yet during the ſixteenth and ſeventeenth centuries it was the favourite chamber inſtrument of every nation in Europe, and in the beginning of dramatic muſic the recitatives were accompanied by the arch-lute, or theorbo, inſtead of the harpſichord.

Sir Thomas Wyat, the elder, one of our beſt early poets, has left us a ſonnet to his lute, written very early in the ſixteenth century; and Congreve, at the end of the ſeventeenth, has celebrated the performance of Mrs. Arabella Hunt on that inſtrument.

The earlieſt mention of the lute that we have found among the moderns is in Boccaccio, *Giornata prima*, where the ſinging is generally ſaid to have been accompanied by the lute. In Chaucer's Pardoner's tale, we are told:

"In Flanders whilom was a compagnie
Of yougè folk that haunted in folie,
As hazard, riot, ſtewès and tavèrnes
Whereas with harpès, lutès, and guitèrnes,
They daunce and play."

In Shakſpeare's firſt part of Henry IV. Mortimer tells his lady, who can ſpeak no Engliſh, that her tongue

"Makes Welſh as ſweet as ditties highly penn'd,
Sung by a fair queen in a ſummer's bower,
With raviſhing diviſion to her lute."

And in lord commiſſioner Whitelocke's MS. narrative of a maſque given in 1633, to Charles I. and his queen, by the four inns of court, he ſays, that "he engaged forty lutes, beſides other inſtruments and voyces of the moſt excellent kind in conſorte."

There was a lute at the Italian opera in England, to the end of Handel's regency. And the place of luteniſt in the king's chapel was continued till the death of Giglier, about the middle of the laſt century.

It ſeems as if in France there had been a time when there was no other inſtruments in uſe than lutes, as *luthier* not only implies the maker of lutes, but violins, violoncellos, and other inſtruments of the ſame kind.

There has been no ſatisfactory etymology given to the word lute, though Scaliger and Bochart have tried to find or frame one, deriving it from the Arabic *allaud*, whilſt others have derived it from the German *laute*, or *lauten*, ſonare.

The ſtringed inſtruments of the ancients were ſo numerous, and ſo various in their forms, that we know not the preciſe difference between the lyre and cithara. The teſtudo, among poets, not only implies the lyre, ſaid to have been originally made by Mercury of the back or hollow ſhell of the *teſtudo aquatica*, or ſea tortoiſe, but muſic itſelf.

As to the different names that may have been given to the ſame kind of inſtrument by the ancients, ſuch as φορμιγξ, χελυς, teſtudo, cithara, &c. we ſhall leave the diſpute, ſays Merſennus, to grammarians, who may conſult Athenæus, Julius Pollux, Ariſtides, Quintilianus, and other Greeks; for ſince we are in poſſeſſion of the inſtrument, they may give it what name they pleaſe.

Vincenzo Galileo (Dial.) ſays the beſt lutes were made in England.

The lute conſiſts of four parts, the table, the body or belly, which has nine or ten ſides, the neck or finger-board, which has nine or ten frets or diviſions marked with catgut or bowel ſtrings, and the head or croſs, where the ſcrews or pins for tightening or relaxing the ſtrings in tuning are faſtened. This is called the lute with two necks, or the theorbo, which has ſometimes only one ſtring to each note. In the middle of the belly or table, there is a roſe or paſſage for the ſound. There is alſo a bridge, to which the ſtrings are faſtened, and a piece of ivory between the head and the neck, to which the other extremities of the ſtrings are fitted.

In performing on the lute, the ſtrings are ſtruck with the right hand, and preſſed upon the frets with the left.

Whoever wiſh to teach themſelves to play upon this inſtrument, as it will be difficult now to find a good maſter, may attain conſiderable knowledge in the practice of it by a peruſal of Père Merſenne's Harmonie Univerſelle, printed at Paris in 1636, folio, livre ii. des Inſtrumens, p. 45; and Mace's Muſick's Monument, folio, 1676, Graſſineau. This laſt book is written in a ſtyle amuſingly quaint; but it probably contains all the eſſential rules known at the time it was written, both for playing, judging of the goodneſs of the inſtrument and ſtrings, placing the frets, &c. But after the deceaſe of honeſt Thomas Mace, whoſe ſtyle much reſembles that of Anthony Wood, though he exceeds him in quaintneſs and ſimplicity, there were probably many refinements diſcovered by great players, both in compoſing for the inſtrument and in performing upon it, which are now quite loſt.

The inhabitants of Congo have a lute of a ſingular kind. The body and neck of this inſtrument reſemble ours; but the belly, that is, the place where the roſe or ſound-hole has place in our lutes, is of very thin parchment; which probably implies that the whole table or belly of this inſtrument is covered with parchment inſtead of wood. It is ſtrung with the hair of an elephant's tail, the ſtrongeſt and the beſt that can be choſen; or elſe with the bark of the palm-tree. The ſtrings reach from one end of the inſtrument to the other, and are faſtened to rings fixed at different places of the lute one above the other. To theſe rings are ſuſpended ſmall plates of iron and ſilver of different ſizes and different tones. In thrumming the ſtrings theſe rings are put in motion, which likewiſe move the little metal plates, and the whole forms a kind of murmuring harmony, or rather a confuſed noiſe, which is pretended not to be diſagreeable. The inhabitants likewiſe add, that in thrumming the ſtrings of this inſtrument in the way we produce ſound from the harp, the muſician expreſſes his thoughts as clearly as if he were ſpeaking. Encycl. Suppl. folio.

Lute, *Archi.* See Arciluto.

Lute, *Theorbo.* See Theorbo.

LUTEA, in *Natural Hiſtory*, the name of a ſpecies of fly found frequently near waters after rain; it is of a duniſh-yellow colour, the wings are long, and the eyes large and prominent; the tail is thick, and has two hairs of a conſiderable length growing at the head, ſo that it is of the biſetæ kind.

Lutea is alſo a name by which ſome authors have called the yellow-hammer. See Emberiza *Citrinella.*

LUTEEFGUR, in *Geography*, a town of Hindooſtan, ſituated in a paſs between the mountains of Benares, where the air is very inſalubrious; 15 miles S.E. of Chunar.

LUTEOLA, in *Botany*, the herb Weld, Dyer's-weed, or Yellow-weed, ſo called from *luteus*, yellow, becauſe it is of very general uſe in various countries for giving that colour to woollen cloth or yarn. See Reseda.

Luteola, in *Ornithology*, a name given by many to a ſmall bird, the Motacilla *Trochilus* of Linnæus (which ſee), called by others *aſilus*, and by others *regulus non criſtatus*; but this laſt is a name that has occaſioned ſome confuſion, as many have erroneouſly called our common wren the *regulus*, and as it has no creſt, imagined it to be the bird meant by this name.

It is, excepting the creſted wren, the ſmalleſt of all European birds, and it very little exceeds that in ſize; its head, neck, and back are of a greeniſh-brown; the rump is greener than the reſt; it has a yellow line on each ſide, extended from the noſtrils, beyond the eyes, to the hinder part of the head; the breaſt, throat, and belly are yellow, with a very faint caſt of green; the wings and tail are brown, and all their feathers are tipped with green at their ends; the under part of the wings has much of a very fine green; the beak is extremely ſlender, and half an inch long; the mouth is yellow within; it makes a loud noiſe, like that of a graſshopper, and is principally found among willows; it is continually creeping and ſinging among the branches of trees; it builds with ſtraw and feathers, and lays five eggs, which are white, and ſpotted with red: there is a conſiderable variation in the colours of theſe birds; ſome of them being much greener on the back, and much whiter on the belly than others.

LUTEREE, in *Geography*, a town of Hindooſtan, in Lahore; 33 miles N. of Jummoo.

LUTHER, Martin, in *Biography*, the celebrated author of the Reformation in Germany, deſcended from parents in very humble circumſtances, was born at Eiſleben, in Saxony, in the year 1483. He diſcovered an early inclination for learning, and having attained the rudiments of grammar under his father's roof, he was ſent to ſchool at Magdeburg, where he continued only about a year, and during that ſhort period he ſupported himſelf, like many other poor German ſcholars, by literally begging his bread. From Magdeburg he went to Eiſenach, in Thuringia, and diſtinguiſhed himſelf in a ſchool of high reputation, by his diligence and proficiency. In 1501 he was entered at the univerſity of Erfurt, and in a very ſhort time, having a mind ſuperior to the ſcholaſtic modes of inſtruction then in uſe, he became diſguſted with thoſe ſubtile and uninſtructive ſciences. He immediately applied himſelf with the greateſt ardour and aſſiduity to the works of the ancient Latin writers, ſuch as Cicero, Virgil, Livy, Salluſt, &c. and ſuch was the ſucceſs with which he ſtudied, that he became the object of admiration to the whole univerſity. He took his degree of M.A. when he was ſcarcely twenty years of age, and immediately afterwards began to read lectures on Ariſtotle's phyſics, on ethics, and other branches of philoſophy. He began now to conſider the profeſſion which he ſhould adopt for his ſupport in life, and, by the perſuaſion of his friends, he turned his attention to juriſprudence; but an accident, to which he was witneſs, *viz.* the death of a friend by the diſcharge of a thunder-cloud, ſo ſenſibly affected him, that he determined to retire from the world into a convent of the Auguſtine friars. No entreaties on the part of his friends could divert him from his plan, which he conceived to be a duty that he owed to God, and accordingly aſſumed the habit of that order. He now applied himſelf very diligently to the ſtudy of theology, and turned his mind ſo eagerly to the reading of the Latin bible, which he had met with by accident, as to excite the moſt lively emotions of ſurpriſe and aſtoniſhment among the monks, who were little accuſtomed to derive their notions concerning religion from that ſource. Having paſſed a year in the monaſtery of Erfurt, he took the vows, and was, in 1507, admitted to prieſts' orders. His great and profound learning, the ſanctity of his moral conduct, and his extenſive knowledge of the holy ſcriptures, were generally known and applauded; and in the following year, Frederick, elector of Saxony, having lately founded an univerſity at Wittemburg, appointed Luther to the profeſſorſhip of philoſophy, and afterwards that of divinity. The duties attached to theſe offices he diſcharged with ſo much ability, and in a method ſo totally different from the uſual mechanical and dull forms of lecturing, that he was crowded with pupils from all quarters, and was regarded as the chief ornament of the univerſity. In 1510, Luther was ſent to Rome by the monks of his order, to get ſome diſputes between them and their vicar-general ſettled by his holineſs the pope. While in that city, he made his obſervations on the pope and the government of the church of Rome; he examined the manners of the clergy, which he ſeverely cenſured, particularly as to the haſty and ſlovenly method which they adopted in performing divine ſervice. The careleſſneſs with which they were accuſtomed to offer up their prayers to Almighty God, he declares excited in his breaſt ſentiments of aſtoniſhment and horror. As ſoon as he had accompliſhed the object of his miſſion he returned to Wittemburg, where, in 1512, he had the degree of doctor of divinity conferred upon him, at the expence of Frederick, elector of Saxony, who frequently attended his pulpit diſcourſes, and was as delighted with his eloquence as ſatisfied with his extraordinary merits. Luther was, at firſt, deſirous of declining the honour offered him, conſidering himſelf too young for ſuch a diſtinction, but his objections were over-ruled, and he was told "that he muſt ſubmit to be thus dignified, inaſmuch as the Almighty had important ſervices to be performed in the church, and through his inſtrumentality." Little did they, who made uſe of this expreſſion, whether in a tone of ſeriouſneſs or levity, imagine how truly its prophetic language ſhould be verified, and how extenſively uſeful his future labours ſhould be, in clearing away the corruptions that had almoſt overwhelmed the Chriſtian world, as it was then called; for real Chriſtianity, as dictated by its meek and holy founder, was as difficult to be diſcerned in the age preceding the great reformer, as it was among the moſt barbarian nations devoted to the ſuperſtitions and idolatry of Greece and Rome.

Under the article Reformation, we ſhall endeavour to exhibit, in its true colours, the ſtate of the papal dominion and church, both with reſpect to the people and clergy, as it exiſted when Luther began his labour; to develope the cauſes which produced ſo important a change in the world; and trace its conſequences with regard to mankind. In the preſent article we ſhall more particularly confine ourſelves to the life and labours of Luther himſelf.

This great man, almoſt as ſoon as he was created doctor of divinity, felt it incumbent on him to ſhew that the title and honour had not been conferred without reaſon. He applied himſelf with all diligence to the duties of the theological chair. He read lectures on the ſeveral books of the ſcriptures. He commented on the epiſtle to the Romans and on the book of Pſalms, and his illuſtrations were ſo ſtriking, that, by the thoughtful and the ſerious, he was regarded as the harbinger of a new day ready to break out after a long night of darkneſs and ignorance; and he led multitudes to think and to reaſon on matters of high importance who had never reflected or thought before beyond the concerns of the preſent world. He oppoſed, with a vehemence that could ſcarcely be withſtood, the errors which had been long current in the church and the ſchools, as truth, ſhewing that the ſcriptures were the only teſt of ſound doctrine and practical morality. He applied himſelf diligently to the ſtudy of the ſcriptures, in their original languages, and encouraged the cultivation of theſe languages in the univerſity, as the only ſure foundation on which a proper knowledge of religion could be built. Luther was a ſtrict diſciplinarian in the college, but he exacted no more from the young men under his inſpection than he ſhewed himſelf an example of in his own moral conduct; and thus, by uniting a practical regard to religious duties, with an earneſt zeal in enforcing them upon the minds of others, he contributed, in an eminent degree, to raiſe the univerſity of Wittemburg to a high degree of reputation, which amply gratified the elector for his munificence in founding it. He had himſelf been early initiated in the Peripatetic philoſophy, then univerſally taught in the ſchools; but his eyes were ſoon opened to its numerous defects and ſilly ſubtleties, and while a profeſſor at Wittemburg, in 1516, he wrote to Jodocus, a zealous Ariſtotelian, who had been his preceptor at Erfurt, ſtating at firſt only his doubts reſpecting the doctrines in which he had been inſtructed, and which, in his turn, it was expected he ſhould teach others. Jodocus, wholly unprepared for ſuch remarks, made with firmneſs, mingled with modeſty, was highly incenſed againſt the author of them, and in his next viſit to Urfurt refuſed to ſee him. Luther had not a mind to be intimidated: even the reſpect which he felt for the inſtructor of his early years forbad him to recede a ſingle ſtep; he had ſet his hands to the plough, and could not look back; he had embarked in the cauſe of reform, and muſt neceſſarily advance, notwithſtanding the difficulties that might be oppoſed to him by his deareſt friends. He accordingly wrote a ſecond letter to Jodocus, in which he gave it as his decided opinion, grounded upon indiſputable evidence, that it would be impoſſible to reform the church, without entirely aboliſhing the canons and decretals, and with them the ſcholaſtic theology, philoſophy, and logic, and inſtituting others in their ſtead.

In early life, Luther, whoſe comprehenſive mind could graſp all ſubjects, had ſtudied the writings of St. Auguſtine, Thomas Aquinas, Duns Scotus, and other celebrated ſchoolmen; and in the diſpute concerning Univerſals, attached himſelf to the party of the Nominaliſts, but maturer age and reflection inſtructed him to treat the whole controverſy with contempt. This has been referred chiefly to his early acquaintance with the ancients, but it was probably owing rather to that peculiar ſtrength and ardour of mind which led him eaſily to diſcover the abſurdity of the prevailing modes of reaſoning, and of judging upon theological and philoſophical ſubjects, and to obſerve with regret and indignation the fatal effects of corrupt philoſophy united with eccleſiaſtical tyranny. Under the article Leo X. we have alluded to the general ſale of indulgences publiſhed by that pontiff: this proved the firſt link in a chain of cauſes which produced a revolution in the ſentiments of mankind, the greateſt, as well as the moſt beneficial that has happened ſince the publication of Chriſtianity. When Leo was raiſed to the papal throne, he found the revenues of the church exhauſted by the vaſt projects of his predeceſſors: he felt no deſire to purſue a ſyſtem of economy; his heart, as we have ſeen, (ſee Leo X.) was intent on aggrandizing his family: to this may be added his love of ſplendour, his taſte for pleaſure, and his munificence in rewarding men of genius and merit, all which involved him in new expences; in order to provide a fund for which, he tried every device that himſelf and friends could invent, to drain the credulous multitude of their wealth. Hence the ſale of indulgences, which pretended to convey to the poſſeſſor, either the pardon of his own ſins, or the releaſe of any one, already dead, in whoſe happineſs he was intereſted, from the pains of purgatory. Leo had not, however, the credit of the invention of this ſyſtem; it may be referred back to the papacy of Urban II., in the eleventh century, who had contrived the lucrative trade, in order that the pope might have the means of recompenſing thoſe who went to join the army of the cruſaders in the Holy Land. They were afterwards granted to thoſe who, being unwilling to ſerve themſelves, hired a ſoldier for that purpoſe, and in a ſhort time they were beſtowed on ſuch as gave money for accompliſhing any pious work enjoined by the holy pontiff.

Julius II. had beſtowed indulgences on all who contributed towards building the church of St. Peter at Rome, which, as we have ſeen, was begun while he ſat upon the papal throne, and as Leo was carrying on that expenſive building, his grant was founded on the ſame pretence. The right of promulgating theſe indulgences in Germany, together with a ſhare in the profits ariſing from the ſale of them, was granted to Albert, elector of Mentz, and archbiſhop of Magdeburg, who, as his chief agent for retailing them in Saxony, employed Tetzel, a Dominican friar of licentious morals, who executed his commiſſion with great zeal and ſucceſs, but without regard to any principles of prudence or decency. At length the trade was carried on with ſo little attention to the intereſts of ſociety, that it became a general wiſh that ſome check ſhould be given to it. Luther was not an inattentive ſpectator: he beheld, with concern and indignation, the artifices of thoſe who ſold, and the folly or ſimplicity of thoſe who purchaſed indulgences. Having examined the ſubject, and finding that the practice derived no countenance from the ſcriptures, he determined openly to proteſt againſt ſuch ſcandalous impoſitions on his deluded countrymen.

In the year 1517, he attacked, with all the vehemence in his power, from the pulpit, in the great church of Wittemburg, the vices of thoſe very monks who dared openly to diſtribute indulgences: he tried their doctrines by the ſtandard of ſcripture, and exhorted his hearers to look for ſalvation to the means appointed by God in his holy word. The boldneſs and fervour with which he uttered his exhortations did not fail to make a deep and laſting impreſſion on the people, who, ſuſpecting the deluſions to which they had been long ſubject, were ready to join any perſon, eſpecially one whoſe character for integrity ſtood ſo high as Luther's, in throwing off a yoke which they were ſcarcely able to endure. Luther was not content with undeceiving the perſons who crowded round his pulpit; he advanced with dignity to a higher authority; he wrote to Albert, elector of Mentz, and archbiſhop of Magdeburg, remonſtrating againſt the falſe opinions, as well as the wicked lives, of the defenders and diſtributors of indulgences, intreating him, in a moſt ſupplicatory tone, to exerciſe the authority veſted in him for correcting theſe evils. The archbiſhop was, however, too deeply intereſted in theſe abuſes to lend a hand in putting an end to them. In addition to his letter, Luther tranſmitted to the prelate ninety-five theſes, which he had propoſed as ſubjects of inquiry and diſputation, and which he had publicly fixed in a church at Wittemburg, with a challenge to the learned to oppoſe on a given day, either in perſon or by writing; and to the whole he added a ſolemn proteſtation of his profound reſpect for the apoſtolic ſee, and implicit ſubmiſſion to its authority. On the appointed day no perſon appeared to conteſt Luther's theſes, which rapidly ſpread all over Germany, and excited univerſal admiration of the boldneſs which he diſcovered in venturing to call in queſtion the papal power and authority, and to attack the Dominicans, armed, as they were, with all the terrors of the inquiſitorial authority. The friars of his own order were delighted with his invectives againſt the monks who ſold indulgences, and were anxious to ſee them expoſed to the hatred and ſcorn of the people; and he was ſecretly encouraged in his proceedings by his ſovereign, the elector of Saxony, who thought they might contribute to give ſome check to the exactions of the court of Rome, which the ſecular princes had been long unſucceſsfully endeavouring to oppoſe. The publication of Luther's theſes brought into the field many zealous champions in defence of the holy church, who were leſs eager for the diſſemination of the truth, than for the profits which exiſting abuſes afforded them, and who accordingly traduced the character of Luther, endeavouring to excite the indignation of the clergy and populace againſt him. Luther, however, was not to be terrified by any meaſures which his preſent adverſaries could adopt: he found a large body of the people adhering to his doctrines, and he was content, in their behalf, to go through evil report as well as good report: he even went ſo far, in a public declaration, as to ſay, "that if the pope and cardinals entertained the ſame opinions with his opponents, and ſet up any authority againſt that of ſcripture, there could be no doubt but that Rome was itſelf the very ſeat of antichriſt, and that it would be happy for thoſe countries which ſhould ſeparate themſelves from her."

It does not appear that, at this early period, Luther had any intention of ſetting himſelf againſt the power of the pope; he even wrote a letter to his holineſs in the moſt reſpectful terms, ſhewing the uprightneſs of his intentions, and the juſtice of the cauſe of which he was the advocate. Shortly after this, by the inceſſant repreſentations of Luther's adverſaries, that the heretical notions he was propagating threatened the moſt fatal miſchiefs to the intereſts of the church, Leo iſſued an order for his appearing at Rome to juſtify himſelf. The judges of his conduct were already appointed and ſelected on account of their hoſtility to him. The reformer, by means of his own petitions, and the interference of thoſe friendly to his cauſe, was allowed to be heard at Augſburg, inſtead of being obliged to travel to Rome. Even here, his avowed enemy, cardinal Cajetan, was appointed to try the merits of the queſtion. Luther arrived at Augſburg in the month of October, 1518, and was immediately admitted into the preſence of the cardinal, who, in their ſeveral interviews, would not condeſcend to argue the matter with a perſon of ſuch inferior rank: but, by the mere dictate of authority, required Luther, by virtue of the apoſtolic powers with which he was inveſted, to retract the opinions which he had advanced, and to ſubmit, without heſitation, to the judgment of the pope. Luther, though, for the moment, ſurpriſed at the demand of recantation, declared that he could not, with a ſafe conſcience, renounce opinions which he believed to be true, nor ſhould any conſideration induce him to do what would be ſo baſe in itſelf and ſo offenſive to God: ſtill, however, he declared his readineſs to ſubmit to the lawful determination of the church. He went much farther: he expreſſed a willingneſs to refer the controverſy to certain univerſities which he named, and promiſed neither to write nor preach concerning indulgences, provided the ſame ſilence with reſpect to them were enjoined on his adverſaries. Theſe offers were rejected by the cardinal, who peremptorily inſiſted upon a ſimple recantation, and, at the ſame time, forbad the reformer to enter again into his preſence, unleſs he came prepared to comply with what he required. As he had no intention to ſubmit, he thought it more prudent to withdraw, which he did in as private a manner as poſſible, having firſt prepared a formal and ſolemn appeal from the pope, who was then ignorant of his cauſe, to the pope, at a time when he ſhould have received more full and explicit information with reſpect to it.

The ſudden departure of Luther enraged the papal legate, who wrote to the elector of Saxony, requiring him to withdraw his protection from ſo ſeditious a perſon, and either to ſend him priſoner to Rome, or to baniſh him from his territories. The elector refuſed to comply with either of theſe requeſts, though with many external profeſſions of eſteem for the cardinal; but he at the ſame time aſſured Luther privately, that he would not deſert him. Being thus ably ſupported, Luther continued to vindicate his opinions, and he gave a challenge to all the inquiſitors to come and diſpute with him at Wittemburg, promiſing them not only a ſafe conduct from the elector, but liberal entertainment, free from all expences, while they continued at that place. In the mean time Leo's ambition urged him to iſſue a bull, by which he attempted, by his papal authority, to put an end to the diſpute about indulgences, and in this public paper, he magnified, almoſt without bounds, the efficacy of indulgences, and imperiouſly commanded all Chriſtians to aſſent to what he delivered, as the doctrine of the Holy Catholic church. Luther was now ſatiſfied that the ſtorm would ſpeedily fall upon him, and therefore had recourſe to the only expedient left him, to ward off the effect of papal cenſures, by appealing from the pontiff to a general council, which he maintained to be ſuperior in authority to the pope. In January 1519 the emperor died, which rendered it expedient for the court of Rome to ſuſpend any direct proceedings againſt Luther; for by this event, the vicariat of that part of Germany, which is governed by Saxon laws, devolved on the elector of Saxony, and was executed by him during the interregnum which preceded the election of the emperor Charles V. Under the adminiſtration of this prince, Luther enjoyed tranquillity, and his opinions were ſuffered to take root, and even to grow up with ſome degree of ſtrength and firmneſs.

Leo now hoped he ſhould be able to bring back Luther to ſubmiſſion and obedience, without having recourſe to harſh meaſures. He accordingly fixed on Charles Miltitz, a Saxon knight, a perſon endowed with much prudence and dexterity, whom he ſent into Saxony, as his legate, to preſent the elector with a golden conſecrated roſe, as a mark of peculiar diſtinction, and alſo to treat with Luther about the means of reconciling him to the court of Rome. Miltitz, by his great addreſs and ſoothing manners, and his encomiums on Luther's character, produced a conſiderable effect on his mind, and he made ſuch conceſſions as proved, that his principles as a reformer were by no means ſteadily fixed. He agreed to obſerve a profound ſilence on the ſubject of indulgences, provided his adverſaries were bound to the ſame meaſures; and he wrote a humble and ſubmiſſive letter to the pope, acknowledging he had carried his zeal and animoſity too far; and he even conſented to publiſh a circular letter, exhorting his followers and adherents to reverence and obey the dictates of the Holy Roman church.

Had the court of Rome been ſufficiently prudent, and accepted this ſubmiſſion of Luther, and prevented its own champions from engaging in the field of controverſy, the cauſe of the reformation would have been loſt. But the inconſiderate zeal of ſome of Luther's opponents, renewed the diviſions which were ſo nearly healed, and obliged Luther and his followers to examine deeper into the enormities which prevailed in the papal hierarchy, as well as the doctrines of the church. During this year a famous controverſy was carried on at Leipſic, on the challenge of Eckius, between himſelf and Carloſtadt, concerning the freedom of the will, and at the ſame time he urged Luther to enter the liſts with him, on the ſubject of the pope's authority and ſupremacy. The challenge was accepted, and on the appointed day the three champions appeared in the field. The aſſembly which met to witneſs the combat was numerous and ſplendid, and each of the combatants conducted himſelf with great ſkill and dexterity; in the courſe of the debate, Luther no doubt was carried farther than he dreamed of going, led on from one argument to another: he at length maintained, that the church of Rome, in the earlier ages, had never been conſidered as ſuperior to other churches, and combated the pretenſions of that church and its biſhop, from the teſtimony of ſcripture, the authority of the fathers, and the moſt approved eccleſiaſtical hiſtorians, and even from the decrees of the council of Nice, while the beſt arguments of his adverſary were derived from ſpurious decretals, none of which could boaſt of an antiquity equal to that of four centuries. Hoffman, the preſident, refuſed to declare on which ſide victory had fallen, and the queſtion was referred to the univerſities of Paris and Erfurt. Eckius clearly ſaw that the auditors generally declared in favour of the arguments made uſe of by his adverſary, and from this moment he breathed fury and revenge againſt Luther. The latter had, however, the happineſs to know, that he had convinced the celebrated Philip Melancthon, at that time profeſſor of the Greek, at the univerſity of Wittemburg, of the juſtice of his cauſe, and he ſoon after found a vigorous auxiliary in Ulric Zuingle, a canon of Zurich, in Switzerland, whoſe extenſive learning and uncommon ſagacity were accompanied with the utmoſt intrepidity and reſolution. The party of reformers now was great in the talents, and illuſtrious in the characters of their leaders, who made, at this period, the utmoſt efforts to draw over Eraſmus to their ſide. The reputation and authority of this great ſcholar were of the higheſt weight in Europe, as well on account of his talents as of his ſtrictures upon the errors of the church, and upon the ignorance and vices of the clergy. He had ſown the ſeeds which Luther cheriſhed and brought to maturity, but was, however, too wary to entangle himſelf ſo deeply in the diſpute as to lead him into any danger. About this time the univerſities of Cologne and Louvain took part againſt Luther, againſt whoſe decrees he immediately wrote with his uſual ſpirit and intrepidity. Eckius likewiſe repaired to Rome, intent on accompliſhing the ruin of Luther, and he thought he had performed the deed when, by his exertions and influence, pope Leo aſſembled the college of cardinals to prepare a ſentence againſt him with ſuch deliberation, as it was hoped no exception could be taken, either with regard to form or matter.

On the 15th of June 1520, the bull was iſſued, in which forty-one propoſitions, extracted from Luther's works, were condemned as heretical and ſcandalous, and all perſons were forbidden to read his writings on pain of excommunication; thoſe who poſſeſſed any of them were commanded, under ſevere penalties, to commit them to the flames. Luther himſelf, if he did not within ſixty days publicly recant his errors, and burn his books, was pronounced an obſtinate heretic, excommunicated, and delivered unto Satan for the deſtruction of the fleſh; and all ſecular princes were required, under pain of incurring the ſame cenſure, to ſeize his perſon, that he might be puniſhed as his crimes ſhould be found to merit. Short-ſighted prieſts, and raſh bigots, contemplated in this ſentence the ruin of Luther, and the termination of thoſe principles which he had eſpouſed; but it has proved fatal only to the church which uttered it, and to the cauſe which it was intended to ſupport. When an account of what had happened was brought to Luther, he was neither diſconcerted nor intimidated, but calmly conſulted the moſt proper means of preſent defence, and future ſecurity. He appealed a ſecond time to a general council, and came to the reſolution of voluntarily renouncing communion with the church of Rome, and in juſtification of his own conduct, which he might well expect would be every where, though not by all perſons, condemned, he expoſed to the world, without the leaſt diſguiſe or ceremony, the abominable corruptions and deluſions of the papal hierarchy; he went ſtill farther, and without heſitation declared, in the moſt ſolemn manner, before the whole world, that the pope was the predicted "man of ſin," the anti-chriſt ſet forth in the writings of the New Teſtament. Being now releaſed from all obedience to the pope, and ſetting himſelf up in oppoſition to his power, he declaimed, without ſcruple, againſt his tyranny, and he exhorted all Chriſtian princes to ſhake off the ignominious yoke, which had been ſo long impoſed on them, but the weight of which neither they nor their fathers could well bear. He made it the theme of his joy and exultation, that he was marked out as an object of eccleſiaſtical indignation, becauſe he had ventured to aſſert and vindicate the liberty of mankind. Luther proceeded from words to acts; Leo had burnt the books of Luther, and he, by way of returning the compliment, aſſembled all the profeſſors and ſtudents of the univerſity of Wittemburg, and with much ceremony, in the preſence of a prodigious multitude of people of all ranks and orders, committed to the flames the pope's bull, and the decretals and canons relating to his ſupreme juriſdiction: the example was ſoon followed in ſeveral cities of Germany. He next collected from the canon law ſome of the moſt extravagant propoſitions with reſpect to the omnipotence of the papal power, and the ſubordination of all ſecular juriſdiction to the authority of the holy ſee, which he publiſhed with a commentary, pointing out the impiety of ſuch tenets, and their evident tendency to ſubvert all civil government. Within a month after this, a ſecond bull was iſſued againſt him, by which he was expelled from communion with the church, for having inſulted the majeſty, and diſowned the ſupremacy of the Roman pontiff. The intimidating power of papal condemnation had now loſt its effect in Germany, and the bull of Leo put his antagoniſt upon the project of founding a church upon principles directly oppoſite to thoſe of Rome, and to eſtabliſh in it a ſyſtem of doctrine and eccleſiaſtical diſcipline, more conſonant with the ſpirit and precepts of the goſpel.

From this time Luther never ceaſed to attack the corruptions of the church of Rome, and his reaſoning made deep impreſſions upon the minds of the people; their reſpect and reverence for ancient inſtitutions and doctrines in which they had been educated were ſhaken. Students crowded from all parts of the empire to Wittemburg, and under Luther, Melancthon, Carloſtadt, and other eminent, and, for the time, truly enlightened profeſſors, imbibed principles, which, on their return, they propagated among their countrymen with zeal and ardour. On the arrival of Charles V. in Germany, the firſt act of his adminiſtration was to aſſemble a diet of the empire at Worms. This meeting was fixed for the ſixth of January 1521; in the circular letter to the different princes, the emperor informed them that the expreſs purpoſe of this meeting, was to concert with them the proper meaſures for checking the progreſs of thoſe new and dangerous opinions, which threatened to diſturb the peace of Germany, and overthrow the religion of their anceſtors. At the ſame time the pope gave notice to the elector of Saxony, of the decree which he had iſſued againſt the hereſies of Luther, and requeſted that he would ſo far concur with him as to cauſe all the writings of Luther to be publicly burnt, and that he would either put the author of them to death, or impriſon him, or at leaſt ſend him to Rome. He ſent a ſimilar meſſage to Wittemburg, but neither the elector nor the univerſity paid any attention to the exhortations of his holineſs. To the elector of Saxony Luther was under infinite obligations, as by him alone was the emperor prevented from taking ſteps, which would have been fatal to the progreſs of his cauſe. As ſoon as the diet was aſſembled at Worms, the papal legates inſiſted that they were bound, without deliberation, to condemn a man whom the pope had already excommunicated as an obſtinate heretic. The emperor in this was ready to acquieſce, but the elector again ſtepped forth in defence of Luther, and not only prevented the publication of any unjuſt edict againſt him, but inſiſted that he ought to have his cauſe tried by the canons of the Germanic church, and the laws of the empire. It was therefore reſolved, that Luther ſhould be ſummoned before the diet, and be allowed a hearing before any final ſentence ſhould be pronounced againſt him. To protect him againſt the violence of his enemies, the emperor, and all the princes through whoſe territories he was to paſs, granted him a ſafe conduct, and Charles himſelf wrote to require his immediate attendance, renewing, in the moſt ſolemn manner, his aſſurances of protection from injury or ill-treatment. Luther had no ſooner received the ſummons than he prepared to obey it. Nor could the remonſtrances of his friends prevent him from running the riſk of being treated as his books had been already treated. Some of them, anxious for his ſafety, reminded him of the fate of the celebrated Huſs under ſimilar circumſtances, and protected by the ſame ſecurity of an imperial ſafe-conduct, and filled with ſolicitude, adviſed and entreated him not to ruſh wantonly into danger. But Luther with calmneſs and dignity replied, "I am lawfully called to appear at Worms, and thither will I go in the name of the moſt high God, though as many devils, as there are tiles on the houſes, were there combined againſt me."

On the 16th of April Luther arrived at Worms, where greater crowds are ſaid to have aſſembled to behold him, than had ever appeared at the emperor's public entry. While he continued in that city, he was not only treated with reſpect, but his apartments were reſorted to by perſons of high rank, and by the princes of the empire. Before the diet he behaved with becoming reſpect; he acknowledged that he had ſometimes been carried away by the ardour of his temper, and that the vehemence of his writings could not always be juſtified. While, however, he readily admitted his errors, he ſhewed no inclination to renounce a ſingle important principle which he had been promulgating, and he diſplayed the utmoſt preſence of mind when he was called on to plead his cauſe before the grand aſſembly, on the 17th and 18th of April. That his reaſonings ſhould not change the minds of thoſe who came to condemn, cannot be a matter of ſurprize, but when he was called on to recant, he ſolemnly declared, that he would neither abandon his principles, nor materially change his conduct, unleſs he were previouſly convinced, by the ſcriptures, or the force of reaſoning, that his ſentiments were erroneous and his conduct unlawful. Enraged at his unbending ſpirit, ſome of the eccleſiaſtics propoſed, notwithſtanding the promiſes made to the contrary, to avail themſelves of the opportunity of having an enemy in their power, to deliver the church at once from ſuch a peſtilent heretic. But the members of the diet and the emperor alſo refuſed to act in a manner that muſt blaſt their character for ever with the world, and Luther was permitted to depart in ſafety. Scarcely, however, had he left the city, when, in the emperor's name, and by the authority of the diet, he was, in a moſt ſevere edict, pronounced an obſtinate heretic, a member cut off from the church, deprived of the privileges which he had enjoyed as a ſubject of the empire, and the ſevereſt puniſhments were denounced againſt thoſe who ſhould receive, entertain, or countenance him, either by acts of hoſpitality, by converſation, or writing, and all were required to concur in ſeizing his perſon, as ſoon as the term of his ſafe-conduct expired. This decree produced ſcarcely any effect; the emperor was too much engaged by the commotions in Spain, and in the wars in Italy and the Low Countries, to attend to Luther, and the ſovereign princes who had not been preſent at the diet, and who felt for the liberties of the empire, and the rights of the Germanic church, treated it with the higheſt indignation, or the utmoſt contempt. Luther was ſtill, to the elector of Saxony, the object of his moſt anxious ſolicitude; and the meaſures which he adopted at this critical juncture, effectually ſecured him from the threatening ſtorm. In conſequence of a preconcerted plan, and, as ſome hiſtorians have imagined, not without the knowledge of the emperor, as Luther was on his journey, near Eiſenach, a number of horſemen in maſks ruſhed out of a wood, and ſurrounding his company, carried him off with the utmoſt ſpeed to the caſtle of Wartenburg. There the noble-minded elector ordered him to be ſupplied with every thing that he could want, but the place of his retreat was kept a profound ſecret. The ſudden diſappearance of Luther not only occaſioned the moſt bitter diſappointment to his adverſaries, but rendered them doubly odious to the people of Germany, who, not knowing what was become of their leader in reformation, conjectured a thouſand things, till at length they were ready to give him up as deſtroyed by the fury of his enemies. Luther was, however, living in peace, and in the enjoyment of whatever was neceſſary to his well being and to his amuſement; he was frequently indulged with the exerciſe of hunting in the company of thoſe who had the charge of him, living in this retirement under the name of Yonker George. During the period of his ſolitude, he tranſlated a great part of the New Teſtament into the German language, wrote and publiſhed tracts in defence of his doctrines, which, as ſoon as they were ſeen, revived and animated the ſpirit of his followers, and wrote frequent letters to his friends; he had alſo, during this period, the ſatisfaction of knowing that his opinions were gaining ground, and that they had already made ſome progreſs in almoſt every city in Saxony. Luther, weary at length of his retirement, appeared publicly at Wittemburg, in March 1522: this ſtep he took without the elector's knowledge or conſent, but he immediately wrote him a letter to prevent the poſſibility of his taking offence, aſſigning as a reaſon, that it was in conſequence of the information which he had received of the proceedings of Carloſtadt, one of his diſciples, who was animated with ſimilar zeal, but poſſeſſed leſs prudence and moderation than his maſter. This perſon, in the abſence of Luther, had attempted to aboliſh the uſe of maſs, to remove images out of the churches, to ſet aſide auricular confeſſion, the invocation of ſaints, and in ſhort had quite changed the doctrine and diſcipline of the church at Wittemburg, all which Luther ſaid was unſeaſonably and raſhly done. At this time the doctrines of the reformer were not known in France; and in England, the ſovereign, Henry VIII., had made the moſt vigorous exertions to prevent them from invading his realms: he even undertook to write them down, in a treatiſe entitled “Of the Seven Sacraments,” &c. This work he preſented to Leo X. in October 1521. The pope was ſo well pleaſed with the royal attempt to confute the arguments of Luther, that he complimented him with the title of “Defender of the Faith.” Whatever reſpect and reverence Luther might ſhew to kings as ſuch, he had none for the arguments of an antagoniſt, though armed with royal authority, and anſwered Henry with much ſeverity, treating his performance in the moſt contemptuous manner. Luther now publiſhed his tranſlation of the ſcriptures, which produced ſudden, and almoſt incredible effects on the people of Germany, and proved more fatal to the church of Rome than all his other works. It was read with the utmoſt avidity by perſons of every rank, who, with aſtoniſhment, diſcovered, how contrary the precepts of Chriſt are to the inventions of his pretended vicegerents, and being in poſſeſſion of the rule and ſtandard of faith, they conceived themſelves qualified to judge of eſtabliſhed opinions, and to pronounce when they were conformable to that ſtandard. About this time, ſeveral imperial cities in Germany aboliſhed the maſs, and the other ſuperſtitious rites of popery, and openly embraced the reformed religion. The elector of Brandenburg, the dukes of Brunſwick and Lunenburg, and the prince of Anhalt, became avowed patrons of Luther's opinions, and countenanced the preaching of them in their territories. Luther now made open war with the pope and biſhops, and to render them as deſpicable as poſſible, he wrote one book againſt the pope's bull, and another againſt the order falſely called the order of the biſhops. The ſame year he wrote to the aſſembly of the ſtates of Bohemia, in which he aſſured them that he was labouring to eſtabliſh their doctrine in Germany, and exhorted them not to return to the communion of the church of Rome. Ferdinand, archduke of Auſtria, the emperor's brother, promulgated a very ſevere edict againſt the tranſlation of the ſcriptures, and forbade all the ſubjects of his imperial majeſty to poſſeſs any copies of it, or of Luther's other works. In this ſtate of things Leo X. died, and was ſucceeded on the papal throne by Adrian VI., who immediately concerted meaſures with his cardinals concerning the beſt means for ſtopping the progreſs of hereſy. The diet of the empire was holden ſoon after at Nuremberg, to which Adrian ſent his brief, in which he obſerves, that he had heard with grief and indignation, that Martin Luther continued to teach the ſame errors, and to publiſh almoſt daily books full of hereſies; that it appeared ſtrange to him that ſo large and ſo religious a nation could be ſeduced by a wretched apoſtate friar; that nothing, however, could be more pernicious to Chriſtendom, and that he therefore accordingly exhorts them to uſe their utmoſt endeavours to make Luther, and the authors of theſe tumults, return to their duty; or, if they refuſe and continue obſtinate, to proceed againſt them according to the laws of the empire.

The admonitions of his holineſs produced no effect whatever, and the diſciples of Luther advanced in their career with exultation and triumph. In 1523, Luther publiſhed ſeveral pieces; among theſe were ſome on the monaſtic life, which he attacked with great ſeverity, and his exhortations, united with much ſtrong ſatire, produced important effects, for ſoon after nine nuns, among whom was Catharine de Bore, whom he afterwards married, eloped from a nunnery and came to Wittemburg, an act that was as highly applauded by the reformer, as it was condemned by the devotees to the Roman church. Luther compares the deliverance of theſe nuns from the ſlavery of monaſtic life to that of the ſouls which Chriſt had delivered by his death. This year two of the followers of Luther were burnt at Bruſſels, and theſe were the firſt who ſuffered martyrdom for his cauſe: and about the ſame time that this tragical event was perpetrated, he wrote a conſolatory letter to three noble ladies at Miſnia, who were baniſhed from the duke of Saxony's court at Friburg, for reading his books.

On the death of Adrian VI., Clement VII. who ſucceeded him, ſent a legate to the diet which was to be held at Nuremberg, to urge the neceſſity of a ſpeedy execution of the edict of Worms: he was unſucceſsful in the object of his miſſion, and found that the German princes, in general, were not at all inimical to the reformation; he accordingly retired to Ratiſbon with the biſhops, and thoſe of the princes who adhered to the cauſe of Rome, where they engaged vigorouſly to execute the edict of Worms in their reſpective dominions. It was in the courſe of this year that the controverſy between Eraſmus and Luther on the doctrine of “free-will” commenced. Eraſmus had been long urged to take up his pen againſt the reformer, though it was with the greateſt reluctance that he yielded to the importunities of the pope and Catholic princes, ſuſpecting that it would not be found the beſt mode of ending the differences, and eſtabliſhing the peace of the church. At length he ſtood forward in defence of the doctrine of free-will, being deſirous to clear himſelf from the ſuſpicion of favouring a cauſe, which he would not wiſh to be thought in any way to favour. His book was entitled a “Conference concerning Free-will,” which was written with much moderation, and without perſonal reflections. To ſoften the anger of Luther, he ſays in his preface, "That he ought not to take it ill that he diſſents from his opinions in particular points, as he had allowed himſelf the liberty of differing from the judgment of popes, univerſities, and doctors in the church." It was ſome time before Luther took up his pen in defence of his own poſitions, but his anſwer was extremely ſevere: he accuſed his opponent of "being careleſs about religion, and little ſolicitous what became of it, provided the world continued in peace, and that his notions were rather philoſophical than dictated by Chriſtian truth." Luther was next engaged in a controverſy with Carloſtadt, reſpecting the euchariſt. Though Luther had renounced the doctrine of "tranſubſtantiation," according to which the bread and wine were changed by conſecration into the body and blood of Chriſt, yet he thought that the partakers of the Lord's ſupper received in ſome myſtical way, with bread and wine, the real body and blood of Chriſt. This doctrine obtained the name of "conſubſtantiation." Carloſtadt, who, as we have ſeen, was the diſciple of Luther, maintained that the body of Chriſt was not actually preſent, but that the bread and wine were no more than external ſigns, or ſymbols, deſigned to excite in the minds of Chriſtians the remembrance of the ſufferings and death of Chriſt, and of the benefits which ariſe from them. This opinion was univerſally embraced by all the friends of the reformation in Switzerland, and by a conſiderable number of its votaries in Germany, but it was the commencement of a controverſy that was carried on with much bitterneſs, which, notwithſtanding the endeavours that were uſed to reconcile the contending parties, terminated at length in a fatal diviſion between thoſe who had embarked together in the ſacred cauſe of religion and liberty, and which contributed to retard the progreſs of the reformation.

In the month of October 1524, Luther threw off the monaſtic habit, which, though not premeditated and deſigned, was regarded as a very proper introduction to a ſtep which he took the following year, *viz.* his marriage to Catharine, the perſon already referred to, who had eloped from the nunnery of Nimptchen. This meaſure expoſed him to much obloquy from his own friends, as well as from the Catholics. He was even aſhamed of it himſelf, and acknowledged that it had made him ſo deſpicable, that he hoped his humiliation would give joy to angels, and be the ſource of vexation to devils. Melancthon found him ſo much afflicted with his paſt conduct, that he wrote ſome letters of conſolation to him. It was not, it was ſaid, ſo much the marriage, as the circumſtances of the time, and the precipitation with which it was done, that occaſioned the cenſures paſſed upon Luther. He married ſuddenly, and at a time when Germany was groaning under the miſeries of a war which had been occaſioned by the introduction of the new doctrines, and which will be noticed under the article REFORMATION. Luther ſoon recovered from the ſtate of abaſement into which he had for a ſeaſon fallen, and then aſſumed his former air of intrepidity, and boldly ſupported what he had done. "I took," ſaid he, "a wife, in obedience to my father's commands, and haſtened the conſummation, to prevent impediments, and ſtop the tongues of ſlanderers."

About this period Luther loſt by death his friend, and the faſt friend of the reformation, Frederic, elector of Saxony; but the blow was leſs ſenſibly felt, as he was ſucceeded by his brother John, a more avowed and zealous, but leſs able, patron of Luther and his doctrines. Frederic had been a kind of mediator between the Roman pontiff and the reformers of Wittemburg, and had always entertained the hope of reſtoring peace in the church, and of ſo reconciling the contending parties, as to prevent a ſeparation either in point of eccleſiaſtical juriſdiction or religious communion: hence, though rather favourable to the innovations of Luther, he took no pains to introduce any change into the churches of his own dominions, nor to ſubject them to his juriſdiction. But his ſucceſſor acted very differently: he ordered a body of laws relating to the form of eccleſiaſtical government, the method of public worſhip, the rank, offices, and revenues of the prieſthood, and other matters of that nature, to be drawn up by Luther and Melancthon, which he afterwards promulgated throughout his dominions. The example of this prince was followed by all the other princes and ſtates of Germany, who renounced the papal ſupremacy and juriſdiction. The Lutherans were now threatened with a grievous perſecution, which the public troubles of Europe only prevented from being carried into execution: they, on the other hand, were not negligent in taking effectual meaſures for defending themſelves againſt the ſuperſtition and violence of their adverſaries, and formed the plan of a confederacy for that prudent purpoſe.

In June 1526, a diet of the empire was held at Spires, at which Ferdinand, the emperor's brother, preſided; Charles being fully occupied with the troubles in Spain and Italy. When the ſtate of religion came before the aſſembly, the emperor's ambaſſadors uſed their utmoſt endeavours to obtain a reſolution, that all diſputes about religion ſhould be ſuppreſſed, and that the ſentence which had been pronounced at Worms againſt Luther and his followers ſhould be put into rigorous execution; but it was agreed, that they could not execute that ſentence, nor come to any determination with reſpect to the doctrines by which it had been occaſioned, before the whole matter was ſubmitted to the cognizance of a general council, lawfully aſſembled. An addreſs to the emperor was unanimouſly agreed on, beſeeching him to aſſemble, without delay, a free and general council; and it was alſo reſolved, that, in the mean time, the princes and ſtates of the empire ſhould, in their reſpective dominions, be at liberty to manage eccleſiaſtical matters in the manner which they ſhould think expedient; yet ſo as to be able to give an account of their adminiſtration to God and the emperor. This was a reſolution the moſt favourable to the cauſe of Lutheraniſm; and ſeveral potentates, whom the dread of perſecution had hitherto prevented from declaring for the reformation, being now delivered from their reſtraint, renounced publicly the ſuperſtition of Rome, and introduced among them the ſame form of religious worſhip, and the ſame ſyſtem of doctrine, which had been received in Saxony. Luther and his fellow-labourers, in the mean time, by their writings, their inſtructions, their admonitions, and counſels, were carrying on their great cauſe with a ſpirit ſuitable to the importance and greatneſs of their undertaking. But this encouraging ſtate of affairs was not of long duration: the emperor began to take meaſures for the recovery of thoſe prerogatives which had been ſnatched from his predeceſſors, and which were neceſſary to the promotion of his ambitious ſchemes. For this purpoſe, he regarded it as neceſſary to ſuppreſs opinions, which might form new bonds of confederacy among the princes of the empire, and unite them by ties ſtronger and more ſacred than any political connection. He accordingly reſolved to employ all the means in his power for the full eſtabliſhment of the religion, of which he was regarded the natural protector; conſidering this as the inſtrument by which he could extend his civil authority. He appointed, for this purpoſe, a diet of the empire to be held at Spires, in the ſpring of 1529, for the expreſs purpoſe of taking into conſideration the ſtate of religion. In that diet the archduke Ferdinand preſided, and had the addreſs to procure a majority approving a decree, which declared it unlawful to introduce any change in the doctrine, diſcipline, or worſhip of the eſtabliſhed religion, before the determinations of a general council were known. This decree was exceedingly revolting to the elector of Saxony, and other princes, as well as to the deputies of fourteen imperial cities, who, in a body, when they found their arguments and remonſtrances of no avail, entered their ſolemn *proteſt* againſt it, on the 19th of April 1529, and appealed to the emperor and a future council. On this account they were diſtinguiſhed by the name of PROTESTANTS, which, from this period, has been applied to all ſects of whatever denomination which have ſeparated themſelves from the Roman church. The proteſting princes ſent embaſſies to the emperor, which were ill received; and in anſwer to one of them, they received an account that he was determined to come into Germany, with a view to terminate, in a diet to be held at Augſburg, in June 1530, the religious diſputes which had produced ſo many and grievous diviſions in the empire. Charles had many conſultations with pope Clement VII. concerning the moſt effectual means for that purpoſe. In theſe interviews the emperor inſiſted, in the moſt urgent manner, on the neceſſity of aſſembling a general council: to this his holineſs was a decided enemy, becauſe he had learnt from hiſtory that general councils were factious, ungovernable, and ſlow in their operations; and he contended that the ſureſt way was for the emperor to do his duty, in ſupporting the authority of the church, and in employing all his power in executing ſpeedy vengeance on the obſtinate heretical factions, who dared to call in queſtion the authority of the holy Roman ſee. Charles was ſtill for mild and conciliatory meaſures, but promiſed if theſe ſhould prove ineffectual, that then he would employ the weight of his authority in reducing the rebellious to implicit obedience. In his journey to Augſburg he had full opportunity of knowing the ſentiments of the people, and, from his own obſervation, he was ſatisfied that ſeverity ought not to be attempted, until other meaſures proved ineffectual: he therefore called on the elector of Saxony to obtain from Luther, and other eminent divines, a written explication of their religious ſyſtem, and an explicit avowal of the ſeveral points in which they differed from the church of Rome. Luther delivered to the elector at Torgaw ſeventeen articles, called "The articles of Torgaw," which were deemed by him a proper declaration of the ſentiments of the reformed. By others they were not thought ſufficiently open, and Melancthon was deſired to give an account of the ſame, who, with a due reſpect to the ſentiments of Luther, expreſſed his opinions, and ſet forth his doctrine, with the greateſt elegance and perſpicuity, and in terms as little offenſive as poſſible to their opponents. Such was the origin of the creed, celebrated in hiſtory as "The confeſſion of Augſburg." In June 1530, the diet was opened; and in a few days, the Proteſtants, who had adopted the opinions of Zuingle, delivered their confeſſion, drawn up by Martin Bucer. A refutation of this was undertaken by Faber, Eckius, and Cochlæus, which was read publicly in the diet; and the unlimited ſubmiſſion of the Proteſtants to the doctrines contained in it was required by the emperor. Inſtead, however, of yielding obedience to the imperial command, they demanded a copy of the paper, in order that they might have an opportunity of demonſtrating more fully its extreme inſufficiency and weakneſs. This requeſt was refuſed, and there was now no proſpect of a reconciliation. The emperor next attempted to bring over to his views the princes who had been ſome time the patrons of the new doctrines: but however deſirous they might be of obliging the emperor, they would not make ſacrifices to him of their integrity, and, in a firm tone, refuſed to abandon what they deemed the cauſe of God, for the ſake of any earthly acquiſition. The emperor, diſappointed and exceedingly vexed, reſolved to take vigorous meaſures for aſſerting the authority and doctrines of the eſtabliſhed church, and enforcing the ſubmiſſion of heretics. He accordingly condemned the peculiar tenets held by the Proteſtants, forbidding any perſon to protect or even tolerate ſuch as taught them, enjoining a ſtrict obſervance of the eſtabliſhed rites, and prohibiting any further innovation under ſevere penalties. This decree, which was regarded as a prelude to the moſt violent perſecution, convinced the Proteſtants that the emperor was reſolved on their deſtruction; and the dread of the calamities which were ready to fall on the church oppreſſed the ſpirit of Melancthon, who reſigned himſelf to a ſettled melancholy. Luther, however, was not at all diſheartened, and uſed his utmoſt efforts to keep up the ſpirits of thoſe who were willing to give way; being aſſured that their perſonal ſafety, as well as ſucceſs, depended wholly on union. In purſuance of this opinion, they aſſembled in 1530, firſt at Smalcalde, and afterwards at Frankfort, where they formed a ſolemn alliance and confederacy, with the reſolution of defending vigorouſly their religion and liberties againſt the dangers with which they were threatened by the edict of Augſburg. They invited the kings of England, France, and Denmark, to join in the confederacy; and, by their negociations, ſecured powerful protection and aſſiſtance, in caſe of neceſſity. Luther was at firſt averſe from this confederacy, dreading the calamities which it might produce. In this ſtate of things, the elector palatine and the elector of Mentz offered their mediation, and endeavoured to reconcile the contending princes; and, in a ſhort time, negociations were carried on, that finally produced a pacification, the terms of which were agreed upon at Nuremburg, and ſolemnly ratified in the diet at Ratiſbon, Auguſt 3d, 1532. By this treaty, the Proteſtant princes engaged to aſſiſt the emperor with all their forces, in reſiſting the invaſion of the Turks; and it was ſtipulated that univerſal peace ſhould be eſtabliſhed in Germany, until the meeting of a general council, the convocation of which the emperor was to endeavour to procure within ſix months; that no perſon ſhould be moleſted on account of religion; that a ſtop ſhould be put to all proceſſes begun by the imperial chamber againſt the Proteſtants; and that the ſentences already paſſed to their detriment ſhould be declared void.

Luther now had the ſatisfaction and happineſs of ſeeing one of the chief obſtacles to the undiſguiſed profeſſion of his opinions removed; and henceforth he might ſit down and contemplate the mighty work which he had accompliſhed: his diſciples and followers, the Proteſtants of Germany, who had hitherto been regarded only as a religious ſect, came to be conſidered as a political body of ſome conſequence. The emperor, in conformity to the ſtipulations of the truce lately concluded, applied to the pope for a general council: but Clement threw a multitude of obſtacles in the way to prevent it; and when he found that to be impoſſible, he inſiſted that the meeting ſhould be held in Italy, but the Proteſtants contended for it in Germany. The latter inſiſted that all matters in diſpute ſhould be determined by the words of Scripture alone; the pope aſſerted that the decrees of the church and the opinions of the fathers were of equal authority. They required a free council, in which the divines, commiſſioned by different churches, ſhould be allowed a voice; he aimed at modelling the council in ſuch a manner as would render it entirely dependent on his pleaſure.

Above all, the Proteſtants thought it unreaſonable that they ſhould bind themſelves to ſubmit to the decrees of a council, before they knew on what principles thoſe decrees were founded, by what perſons they were to be pronounced, and what forms of proceeding they would obſerve. The pope maintained it would be unneceſſary to call a council, unleſs thoſe who demanded it previouſly declared their reſolution to acquieſce in its decrees. The meeting was accordingly poſtponed during the pontificate of Clement VII.

In 1533 Luther wrote a conſolatory epiſtle to ſome perſons who had ſuffered hardſhips for adhering to the Augſburg confeſſion of faith, in which he ſays, “ The devil is the hoſt, and the world is his inn ; ſo that wherever you come, you will be ſure to find this ugly hoſt.” He had alſo, about this time, a terrible controverſy with George, duke of Saxony, who had ſuch an averſion to the doctrines promulgated by Luther, that he obliged his ſubjects to take an oath that they would never embrace them. At Leipſic there were found ſixty or ſeventy perſons, who could not be reſtrained within the boundaries of the eſtabliſhed creed, and it was diſcovered that they had conſulted Luther about it ; upon which the duke complained to the elector, that Luther had not only abuſed his perſon, but had preached up rebellion among his ſubjects. Luther refuted the accuſation, by proving that he had been ſo far from ſtirring up his ſubjects againſt him, on the ſcore of religion, that he had exhorted them rather to undergo the greateſt hardſhips, and even ſuffer themſelves to be baniſhed. In the following year, the bible, tranſlated by Luther into the German, was firſt printed, with the privilege of the elector ; and it was publiſhed the year after. He likewiſe gave to the world a book againſt maſſes, and the conſecration of prieſts, in which he relates a conference which he had with the devil upon thoſe points : for it is a circumſtance worthy of obſervation, that, in the whole hiſtory of this great man, he never had any conflicts of any kind, but the devil was always his antagoniſt. In 1535 the new pope Paul III. was applied to for a general council ; and in the hope of preventing it, he appointed Mantua as the proper place. To this ſome of the Catholic ſovereigns, and all the German Proteſtants, ſtrongly objected ; being fully perſuaded that, in ſuch a council, nothing would be concluded but what would be agreeable to the ſentiments and ambition of the pontiff ; and they demanded the performance of the emperor's promiſe, that they ſhould have a council in Germany. At the ſame time, that they might not be taken by ſurpriſe, they deſired Luther to draw up a ſummary of their doctrine, in order to preſent it to the aſſembled biſhops, if it ſhould be required of them. This ſummary, which was diſtinguiſhed by the name of “ The articles of Smalcalde,” from the place at which they were aſſembled, is generally joined with the creeds and confeſſions of the Lutheran church. While our reformer was buſily engaged in this work, he was ſeized with a grievous and very painful diſeaſe, a fit of the ſtone and obſtruction of the urine, which continued ſo long as to give his friends ſerious apprehenſions for his life. In the midſt of his agonies, and after eleven days' torture, without the ſmalleſt relief, he ſet out, contrary to the advice of his friends, on his return home. The motion of the carriage, which it was expected would prove fatal to him, was the cauſe of removing the evil under which he was labouring. In the year 1538, as a general aſſembly ſeemed impracticable, the pope, that he might not ſeem to neglect that degree of reformation which was unqueſtionably within his power, deputed a certain number of cardinals and biſhops, with full authority, to inquire into the abuſes and corruptions of the Roman court, and to propoſe the moſt effectual method of removing them. It was intended to do as little as poſſible : ſtill a multitude of enormities were unveiled, an account of which was ſoon tranſmitted into Germany, much to the ſatisfaction of the Proteſtants there. This inveſtigation, partial as it was, proved the neceſſity of a reformation in the head as well as the members of the church ; and it even pointed out many of the corruptions, againſt which Luther had remonſtrated with the greateſt vehemence. It was, however, intended only as a farce, and as ſuch Luther treated it ; and to ridicule it more ſtrongly, he cauſed a caricature to be drawn, in which was repreſented the pope ſeated on a high throne, ſome cardinals about him with foxes' tails, with which they were bruſhing off the duſt on all ſides. Luther publiſhed, about the ſame time, “ A Confutation of the pretended Grant of Conſtantine to Sylveſter, biſhop of Rome ; and alſo ſome Letters of John Huſs, written from his Priſon at Conſtance, to the Bohemians.” On the death of George, duke of Saxony, the ſucceſſion devolved on his brother Henry, who was zealouſly attached to the Proteſtant religion, and who, notwithſtanding a clauſe in his brother's will, by which he bequeathed all his territories to the emperor and the king of the Romans, ſhould Henry make any attempt to introduce innovations, immediately invited Luther and ſome other Proteſtant divines to Leipſic. By their aid and advice he quickly overturned the whole ſyſtem of Popiſh rites and doctrines, and eſtabliſhed the full exerciſe of the reformed religion, with the univerſal applauſe of his ſubjects, who had long wiſhed for this change. By this revolution, the whole of Saxony was brought within the Proteſtant pale.

Luther was inceſſantly employed, till his death, in promoting the cauſe of which he was the great founder. In the year 1546, he, in company with Melancthon, paid a viſit to his own country, which he had not ſeen before for many years, and he returned in ſafety ; but in a ſhort time after, he was called thither by the earls of Mansfeldt, to compoſe ſome differences which had ariſen about their boundaries. Though he had not been accuſtomed to ſuch kind of buſineſs, yet he would not refuſe the ſervice which he might be able to render by his advice and authority. On this occaſion he met with a ſplendid reception, uſed his beſt endeavours to ſettle the matters in diſpute, and ſometimes officiated in the church ; but the ſtate of his health was ſo precarious, that it was feared every great effort would prove fatal to him. His laſt public ſervice was in the church, where he was ſeized with a violent inflammation in the ſtomach. His natural intrepidity did not forſake him ; and his laſt converſation with his friends was concerning the happineſs reſerved for good men in a future life. On the morning of the 12th of February 1546, being awakened from a ſound ſleep by his diſorder, and perceiving his end to be approaching, he commended his ſpirit into the hands of God, and quietly departed this life at the age of ſixty-three. He did not forget his cauſe even in his dying moments, but admoniſhed thoſe about him to pray to God for the propagation of the goſpel ; “ becauſe,” ſaid he, “ the council of Trent, which has ſat once or twice, and the pope, will deviſe ſtrange things againſt it.” Immediately after his deceaſe, the body was put into a leaden coffin, and carried with funeral pomp to the church at Eiſleben, when Dr. Jonas preached a ſermon on the occaſion. The earls of Mansfeldt requeſted that his body might be interred in their territories ; but the elector of Saxony inſiſted upon his being brought back to Wittemburg, which was accordingly done, and he was buried there with greater pomp than had been known to have accompanied the funeral of any private man. Princes, earls, nobles, and ſtudents without number, attended the proceſſion, and Melancthon delivered a funeral diſcourſe. He left ſeveral children by his wife Catharine de Bore. Innumerable were the calumnies invented by his enemies reſpecting his death, his principles, and his conduct, which it is needleſs for us to repeat, as they have been amply refuted by the moſt reſpectable hiſtorians. The zeal and madneſs of the Papiſts againſt their formidable antagoniſt, who had ſhaken to the foundation the pillars of their faith, did not ceaſe with his death. They urged the emperor Charles V., while with his army at Wittemburg, to cauſe the monument erected to his memory to be demoliſhed, and his bones to be dug up and burnt with every indignity; but the mind of Charles was ſuperior to ſuch childiſh and malignant acts, and he inſtantly forbad that any inſult ſhould be offered to his tomb, or his remains, upon pain of death. "I have," ſaid the emperor, "nothing farther to do with Luther: he is henceforth ſubject to another judge, whoſe juriſdiction it is not lawful for me to uſurp. Know, that I make not war with the dead, but with the living, who are ſtill in arms againſt me." We cannot bring this article to a cloſe, without referring to the teſtimonies of the learned and the wiſe reſpecting the character of Luther, who introduced, not into Germany only, but into the world, a new and moſt important era, and whoſe name can never be forgotten while any thing of principle remains that is deſerving of remembrance. It muſt not be overlooked, that the grand and leading doctrine of Lutheraniſm, and that on which the permanent foundation of the reformed religion was laid, is the right of private judgment in matters of religion. To this, as we have ſeen, he was at all times ready to devote his talents, his character, and his life; and ſays the biographer of Leo X., "the great and imperiſhable merit of the reformer conſiſts in his having demonſtrated it by ſuch arguments, as neither the efforts of his adverſaries, nor his own ſubſequent conduct, have been able either to confute or invalidate." In paſſing judgment upon the characters of men, ſays Robertſon, we ought to try them by the principles and maxims of their own age, and not by thoſe of another: for although virtue and vice are at all times the ſame, manners and cuſtoms are continually varying. Some parts of Luther's behaviour, which to us appear moſt culpable, gave no diſguſt to his contemporaries. It was even by ſome of thoſe qualities, which we are now apt to blame, that he was fitted for accompliſhing the great work in which he embarked.

Luther himſelf was ſenſible of defects, which he pathetically acknowledges in an addreſs to the reader of his works: "I intreat you," ſays he, "to read my writings with cool conſideration, and even with much pity. I wiſh you to know that when I began the affair of indulgences, I was a monk, and a moſt mad papiſt. So intoxicated was I, and drenched in papal dogmas, that I would have been moſt ready at all times to murder, or aſſiſt in murdering, any perſon who ſhould utter a ſyllable againſt the pope. I was always earneſt in defending doctrines I profeſſed. I went ſeriouſly to work, as one who had a horrible dread of the day of judgment, and who from his inmoſt ſoul was anxious for ſalvation. You will find, therefore, in my earlier writings, with how much humility, on many occaſions, I gave up conſiderable points to the pope, which I now deteſt as blaſphemous and abominable in the higheſt degree. This error my ſlanderers may call inconſiſtency; but you, my pious readers, will have the kindneſs to make ſome allowance, on account of the times, and my own inexperience. I ſtood abſolutely alone at firſt, and certainly was very unlearned, and very unfit to undertake matters of ſuch vaſt importance. It was by accident, not willingly or by deſign, that I fell into thoſe violent diſputes. God is my witneſs."

"Martin Luther, reſenting an affront put on his order, began to preach againſt abuſes in the ſale of indulgences, and being naturally of a fiery temper, and provoked by oppoſition, he proceeded even to deſcry indulgences themſelves, and was thence carried, by the heat of diſpute, to queſtion the authority of the pope. Still, as he enlarged his reading, in order to ſupport theſe tenets, he diſcovered ſome new abuſe or error in the church of Rome, and finding his opinions greedily hearkened to, he promulgated them by writing, diſcourſe, ſermons, conference, and daily increaſed the number of his diſciples. All Saxony, all Germany, all Europe, were in a little time filled with the voice of this daring innovator; and men, rouſed from that lethargy in which they had ſo long ſlept, began to call in queſtion the moſt ancient and received opinions. The elector of Saxony, favourable to Luther's doctrine, protected him from the violence of the papal juriſdiction: the republic of Zurich even reformed their church according to the new model: many ſovereigns of the empire, and the imperial edict itſelf, ſhewed a favourable diſpoſition towards it: and Luther, a man naturally inflexible, vehement, and opinionative, was become incapable, either from promiſes of advancement or terrors of ſeverity, to relinquiſh a ſect of which he himſelf was the founder, and which brought him a glory ſuperior to all others, the glory of dictating the religious faith and principles of multitudes."

Dr. Campbell, in his lectures on Eccleſiaſtical Hiſtory, has rendered our reformer his teſtimony of reſpect and gratitude; but as this is conveyed in ſentiments and language but little different from the obſervations of Dr. Robertſon, we ſhall extract the account from the latter rather than the former: "As he was raiſed up by Providence to be the author of one of the greateſt and moſt intereſting revolutions in hiſtory, there is not any perſon, perhaps, whoſe character had been drawn with ſuch oppoſite colours. In his own age, one party, ſtruck with horror and inflamed with rage, when they ſaw with what a daring hand he overturned every thing which they held to be ſacred, or valued as beneficial, imputed to him not only all the defects and vices of a man, but the qualities of a dæmon. The other, warmed with admiration and gratitude, which they thought he merited as the reſtorer of light and liberty to the Chriſtian church, aſcribed to him perfections above the condition of humanity, and viewed all his actions with a veneration, bordering on that which ſhould be paid only to thoſe who are guided by the immediate inſpiration of heaven. It is his own conduct, not the undiſtinguiſhing cenſure, or the exaggerated praiſe of his contemporaries, that ought to regulate the opinions of the preſent age concerning him. Zeal for what he regarded as truth, undaunted intrepidity to maintain his own ſyſtem, abilities, both natural and acquired, to defend his principles, and unwearied induſtry in propagating them, are virtues which ſhine conſpicuouſly in every part of his behaviour, that even his enemies muſt allow him to have poſſeſſed them in an eminent degree. To theſe may be added, with equal juſtice, ſuch purity, and even auſterity of manners, as became one who aſſumed the character of a reformer; ſuch ſanctity of life as ſuited the doctrine which he delivered, and ſuch perfect diſintereſtedneſs as affords no ſlight preſumption of his ſincerity. Superior to all ſelfiſh conſiderations, a ſtranger to all the elegancies of life, and deſpiſing its pleaſures, he left the honours and emoluments of the church to his diſciples, remaining ſatisfied himſelf in his original ſtate of profeſſor of the univerſity, and paſtor of the town of Wittemburg, with the moderate appointments annexed to each. His extraordinary qualities were allayed with no inconſiderable mixture of human frailty, and human paſſions. Theſe, however, were of a nature, that they cannot be imputed to malevolence or corruption of heart, but ſeem to have taken their riſe from the ſame ſource with many of his virtues. Accuſtomed himſelf to conſider every thing as ſubordinate to truth, he expected the ſame deference for it from other men; and, without making any allowances for their timidity or prejudices, he poured forth againſt ſuch as diſappointed him in this particular, a torrent of invective and abuſe. Regardleſs of any diſtinction of rank or character when his doctrines were attacked, he chaſtiſed all his adverſaries indiſcriminately, with the ſame rough hand; neither the royal dignity of Henry VIII. nor the eminent learning and abilities of Eraſmus, ſcreened them from the ſame groſs abuſe with which he treated Tetzel or Eckius. To rouſe mankind, when ſunk in ignorance and ſuperſtition, and to encounter the rage of bigotry armed with power, required the utmoſt vehemence of zeal, as well as a temper daring to exceſs. A gentle call would neither have reached, nor have excited thoſe to whom it muſt have been addreſſed. A ſpirit more amiable but leſs vigorous than Luther's would have ſhrunk back from dangers which he braved and ſurmounted. Towards the cloſe of Luther's life, though without any perceptible diminution of his zeal and abilities, the infirmities of his temper increaſed upon him, ſo that he grew daily more peeviſh, more iraſcible, and more impatient of contradiction. Having lived to be a witneſs of his own amazing ſucceſs; to ſee a great part of Europe embrace his doctrines, and to ſhake the foundation of papal Rome, before which the mightieſt monarchs had trembled, he diſcovered, on ſome occaſions, ſymptoms of vanity and ſelf-applauſe. He muſt have been, indeed, more than man, if, upon contemplating all that he actually accompliſhed, he had never felt any ſentiment of this kind riſing in his breaſt." There is yet another teſtimony to the life and labours of this great man that we cannot omit:

"Martin Luther's life," ſays biſhop Atterbury, "was a continual warfare; he was engaged againſt the united forces of the papal world, and he ſtood the ſhock of them bravely, both with courage and ſucceſs. He was a man certainly of high endowments of mind and great virtues: he had a vaſt underſtanding which raiſed him up to a pitch of learning unknown to the age in which he lived; his knowledge in ſcripture was admirable, his elocution manly, and his way of reaſoning with all the ſubtilty that theſe plain truths he delivered would bear, his thoughts were bent always on great deſigns, and he had a reſolution fitted to go through with them, and the aſſurance of his mind was not to be ſhaken or ſurpriſed, and that παρρησια of his (for I know not what elſe to call it) before the diet of Worms, was ſuch as might have become the days of the apoſtles. His life was holy, and, when he had leiſure for retirement, ſevere; his virtues active chiefly, and homilitical, and not thoſe lazy ſullen ones of the cloiſter. He had no ambition but in the ſervice of God: for other things, neither his enjoyment nor wiſhes ever went higher than the bare conveniences of living. He was of a temper particularly averſe to covetouſneſs, or any baſe ſin, and charitable even to a fault, without reſpect to his own occaſions. If, among this crowd of virtues, a failing crept in, we muſt remember that an apoſtle himſelf had not been irreproachable; if, in the body of his doctrine, one flaw is to be ſeen, yet the greateſt lights of the church, and in the pureſt times of it, were, we know, not exact in all their opinions. Upon the whole, we have certainly great reaſon to break out in the phraſe of the prophet and ſay, "How beautiful, upon the mountains, are the feet of him that bringeth glad tidings." Gibbon, ſpeaking of the effects produced by the exertions of Luther and his contemporaries, ſays, "The philoſopher muſt own his obligations to theſe fearleſs enthuſiaſts. 1. By their hands the lofty fabric of ſuperſtition, from the abuſe of indulgences to the interceſſion of the Virgin, has been levelled with the ground. Myriads of both ſexes of the monaſtic profeſſion were reſtored to liberty and the labours of ſocial life. 2. The chain of authority was broken which reſtrains the bigot from thinking as he pleaſes, and the ſlave from ſpeaking as he thinks. The popes, fathers, and councils were no longer the ſupreme and infallible judges of the world; and each Chriſtian was taught to acknowledge no law but the ſcriptures, no interpreter but his own conſcience."

The works of Luther, in the Latin and German languages, were collected and publiſhed in an uniform edition, at Jena, in 1556, in four volumes folio; and in 1572 they were printed at Wittemburg, in ſeven volumes folio. Luther left behind him three ſons and a widow. The latter ſurvived him nearly ſeven years. When the war broke out Catharine wandered about in exile with her children, in difficulties and dangers: ſhe experienced the ingratitude of many, from whom expecting kindneſſes, on account of her huſband's great merits towards the church, ſhe was frequently diſappointed. At length, the plague raging at Wittemburg, and the infection having reached her own houſe, ſhe removed to Torgau, that ſhe might preſerve her children from the diſorder. On her way thither the horſes in the carriage took fright; to avoid, what ſhe conceived, a greater danger, ſhe leaped into the road, and falling into a pool of water, was dreadfully bruiſed, and contracted an illneſs, which in a few weeks terminated her life. Preface to Luther's works: MS. tranſlation of Melchior Adams Life of Luther. Bayle. Robertſon. Hume. Gibbon.

Martin Luther, with reſpect to eccleſiaſtical muſic, being himſelf a lover and judge of the art, was ſo far from baniſhing it from the church, that he augmented the occaſion for its uſe. In 1521 he procured the abolition of the ancient maſs at Wittemburg. In 1523 Lutheraniſm was eſtabliſhed in Denmark and Sweden; and, in 1525, Saxony, Brunſwick, Heſſe, Straſburg, and Frankfort. But though he inſtituted a new liturgy, the eccleſiaſtical tones ſtill regulated the muſic of his church at the time of the reformation, and moſt of the old melodies to the evangelical hymns are compoſed in ſome of them.

The Cantaten, or anthems and ſervices of the reformed church, in the German language, are, however, as elaborate and florid as the motets to Latin words, uſed in Italy during the celebration of the maſs. But in the hymnologia, and metrical pſalmody of this, as well as all other Proteſtant churches, there ſeems to have been one common principle, totally inimical to poetry, which is that of deſtroying all quantity and diſtinction of ſyllables, by making them all of the ſame length.

"Theſe *equal ſyllables* alone admire,
Though oft the ear the open vowels tire."
Pope.

The modern Methodiſts, indeed, have introduced a light and ballad-like kind of melody into their tabernacles, which ſeems as much wanting in reverence and dignity, as the pſalmody of other ſects in poetry and good taſte.

Muſic, in itſelf an innocent art, is ſo far from corrupting the mind, that, with its grave and decorous ſtrains, it can calm the paſſions, and render the heart more fit for ſpiritual and pious purpoſes; particularly when united with language, and the precepts of religion. It has been ſaid, not improperly, that "Muſic, conſidered abſtractedly, is in itſelf a language;" and we may add, that it is more univerſally underſtood by mankind in general, whoſe nerves vibrate in uniſon with its ſelected tones, than any other language among all the dialects of the earth. That articulation muſt be rough and violent indeed, which, without ſinging, can eaſily be comprehended in buildings ſo vaſt as ſome of the Chriſtian churches; in ſuch, it is the *ſpirit*, not the *letter* of ſupplication or thankſgiving, which muſt employ the mind. St. Paul ſays, "I will ſing with the *ſpirit*, and I will ſing with the *underſtanding* alſo." As there never was a national religion without muſic of ſome kind or other, the diſpute concerning that which is moſt fit for ſuch ſolemnities, is reduced to one ſhort queſtion. If muſic be admitted into the ſervice of the church, is that ſpecies of it which the moſt poliſhed part of mankind regard as *good*, or that which they regard as *bad*, the moſt deſerving of ſuch an honour?

That metrical pſalmody, in ſlow notes of equal length, had its origin in Germany, and was brought thence by reformers to other parts of Europe, is demonſtrable: for the 128th Pſalm, "Beati omnes qui timent Dominum," had been tranſlated into German verſe, in order to be ſung in this manner, by John Huſs, in the beginning of the fifteenth century; which tranſlation was afterwards modernized in the ſame meaſure, and to the ſame tune, by Luther. And the ſame melody which we ſing to the 100dth pſalm, is not only given to the 134th, in all the Lutheran pſalm-books, but by Goudimel and Claude le Jeune, in thoſe of the Calviniſts; which nearly amounts to a proof that this favourite melody was not produced in England. It is ſaid to have been the opinion of Handel, that Luther himſelf was its author; but of this we have been able to procure no authentic proof. Tradition, however, gives to this celebrated Hereſiarch, as he is called by the Roman Catholics, ſeveral of the ancient melodies which are ſtill uſed in Germany.

LUTHERANISM, in *Eccleſiaſtical Hiſtory*, the ſentiments of Dr. Martin Luther, and his followers, with regard to religion. See the biographical article LUTHER, under which article we have given an account of the life and labours of this eminent reformer; and of the commencement and foundation of that memorable rupture and revolution in the church, which humbled the grandeur of the lordly pontiffs, and eclipſed ſo great a part of their glory. See REFORMATION.

It has been ſaid indeed by F. Paul, in his Hiſtory of the Council of Trent, p. 5, and after him by Mr. Hume, in his Hiſtory of England, vol. i. p. 119, as well as by others, that the Auſtin friars had been uſually employed in preaching indulgences in Saxony; but that Arcemboldi, a Genoeſe merchant, who was employed by Magdalen, the ſiſter of Leo, to whom he had granted the profits ariſing from the ſale of indulgences in Saxony, to collect the money which ſhould be raiſed, and his deputies, hoping to gain more by committing this truſt to the Dominicans, had bargained with Tetzel; and that Luther was prompted at firſt to oppoſe Tetzel and his aſſociates, and to deny indulgences, by a deſire of taking revenge for this injury offered to his order. Such was the repreſentation of Boſſuet; and other writers, miſled by his authority, have circulated a ſimilar opinion. It is proper, therefore, to obſerve, that the profits ariſing from indulgences in Saxony and the adjacent countries were granted, not to Magdalen, the ſiſter of Leo, but to Albert, archbiſhop of Mentz, who had the ſole right of nominating thoſe who publiſhed them: moreover, Arcemboldi never had any concern in the publication of indulgences in Saxony; becauſe his diſtrict was Flanders and the Upper and Lower Rhine. Beſides, the publication of indulgences in Germany was not uſually committed to the Auguſtinians: from the year 1229, that lucrative commiſſion was principally intruſted with the Dominicans; and they had been employed in the ſame office a ſhort time before the preſent period: the promulgation of them, at three different periods under Julius II. was granted to the Franciſcans, and the guardian of the Franciſcans was joined in the truſt with Albert on this occaſion, though he refuſed to accept it: and it is remarkable, that for half a century before Luther, *viz.* from 1450 to 1517, the name of an Auſtin friar employed in this ſervice occurs but once. To theſe facts it may be added, that it is far from being probable, that Luther would have been ſolicitous about obtaining for himſelf or his order, a commiſſion of this kind, at a time when the preaching of indulgences was become very unpopular; inſomuch that all the princes of Europe, and many biſhops, as well as other learned men, abhorred the traffic; and even the Franciſcans and Dominicans, towards the concluſion of the fifteenth century, oppoſed it publicly, both in their diſcourſes and writings: nor was this commiſſion given to the Dominicans in general, but ſolely to Tetzel. Finally, Luther was never accuſed of oppoſing the publication of indulgences from reſentment or envy, either in the edicts of the pontiffs of his time, or in the reproaches of his contemporary writers, who defended the cauſe of Rome from the year 1517 to 1546, and who were far from being ſparing of their invectives and calumnies. The reader may find this matter fully ſtated by Dr. Maclean, the tranſlator of Moſheim's Eccleſiaſtical Hiſtory, in vol. iv. p. 31. note (*p*) 8vo. edit. 1790, and by Dr. Robertſon in his Hiſt. of Ch. V. vol. ii. p. 125. note (*), 8vo. edit.

Lutheraniſm was formed in the manner ſtated under the article LUTHER; the adherents to which were called Lutherans, from Lutherus, a name which has a Greek turn, and which this great reformer aſſumed in lieu of his family name *Lotter*, or *Lauther*; it being the cuſtom of thoſe days for men of learning to give themſelves Greek names; ſuch were Eraſmus, Melancthon, Bacon, &c.

For a full and accurate account of the riſe and progreſs of Lutheraniſm, the reader may conſult Moſheim and Robertſon, ubi ſupra. See PROTESTANTS and REFORMATION.

Lutheraniſm has undergone ſome alteration ſince the time of its founder. Luther rejected the epiſtle of St. James, as inconſiſtent with the doctrine of St. Paul, in relation to juſtification; he alſo ſet aſide the Apocalypſe; both which are now received as canonical in the Lutheran church.

Luther reduced the number of ſacraments to two, *viz.* baptiſm, and the euchariſt; but he believed the impanation, or conſubſtantiation: that is, that the matter of the bread and wine remain with the body and blood of Chriſt; and it is in this article, that the main difference between the Lutheran and Engliſh churches conſiſts.

Luther maintained the maſs to be no ſacrifice; he exploded the adoration of the hoſt, auricular confeſſion, meritorious works, indulgences, purgatories, the worſhip of images, &c. which had been introduced in the corrupt times of the Romiſh church. He alſo oppoſed the doctrine of free-will; maintained predeſtination; aſſerted that we are neceſſitated in all we do; that all our actions done in a ſtate of ſin, and even the virtues themſelves of heathens, are crimes; that we are only juſtified by the imputation of the merits and ſatisfaction of Chriſt. He alſo oppoſed the faſtings in the Romiſh church, monaſtical vows, the celibacy of the clergy, &c.

Some authors reckon thirty-nine different ſects, which at different times have ſprung up among the Lutherans.

LUTHERANS, a ſect of Proteſtants who profeſs Lutheraniſm, or adhere to the doctrine and tenets of Luther.

The Lutherans, of all Proteſtants, are thoſe who differ leaſt from the Romiſh church; as they affirm, that the body and blood of Chriſt are materially preſent in the ſacrament of the Lord's ſupper, though in an incomprehenſible manner; and likewiſe repreſent ſome religious rites and inſtitutions, as the uſe of images in churches, the diſtinguiſhing veſtments of the clergy, the private confeſſion of ſins, the uſe of wafers in the adminiſtration of the Lord's ſupper, the form of exorciſm in the celebration of baptiſm, and other ceremonies of the like nature, as tolerable, and ſome of them as uſeful. The Lutherans maintain, with regard to the divine decrees, that they reſpect the ſalvation or miſery of men, in conſequence of a previous knowledge of their ſentiments and characters, and not as free and unconditional, and as founded on the mere will of God. Towards the cloſe of the laſt century, the Lutherans began to entertain a greater liberality of ſentiment than they had before adopted; though in many places they perſevered longer in ſevere and deſpotic principles than other Proteſtant churches. Their public teachers now enjoy an unbounded liberty of diſſenting from the deciſions of thoſe ſymbols or creeds, which were once deemed almoſt infallible rules of faith and practice, and of declaring their diſſent in the manner they judge the moſt expedient. Moſheim attributes this change in their ſentiments to the maxim, which they generally adopted, that Chriſtians were accountable to God alone for their religious opinions; and that no individual could be juſtly puniſhed by the magiſtrate for his erroneous opinions, while he conducted himſelf like a virtuous and obedient ſubject, and made no attempts to diſturb the peace and order of civil ſociety. Eccl. Hiſt. vol. iv. p. 440. Eng. ed. 8vo.

LUTHERN, from the French *lucarne*, of the Latin *lucerna*, *light*, or *lantern*, a kind of window over the cornice, in the roof of a building; ſtanding perpendicularly over the naked of the wall; and ſerving to illuminate the upper ſtory.

The French architects diſtinguiſh theſe into various kinds, according to their various forms; as *ſquare*, *ſemicircular*, *bulls' eyes*, *flat arches*, *Flemiſh lutherns*, &c.

LUTHIER, *Fr.* implies not only a lute maker, but a maker of all ſtringed and bowed inſtruments.

LUTI, Benedetto, in *Biography*, a Florentine, was the diſciple of Gabbiani, and from him went to Rome, to put himſelf under the direction of Ciro Ferri; but being diſappointed by his death, formed a ſtyle of his own, the reſult of various imitations; ſelect in deſign, amene and lucid in colour, well contraſted by maſſes of light and ſhade, and harmonious to the eye.

He painted not without merit in freſco, and with greater merit in oil "Cain flying from his murdered Brother," has ſomething of the ſublimity and the pathos that ſtrike in the Pietro Martyre of Titian, and his Pſyche in the gallery of the Capitol, breathing refinement of taſte and elegance. He died in 1724, at the age of 58. Fuſeli's Pilkington.

LUTKENBORG, in *Geography*, a town of the duchy of Holſtein; 30 miles N. of Lubeck.

LUTOMIRSK, a town of the duchy of Warſaw; 18 miles S.S.E. of Lenciez.

LUTON, a conſiderable market-town and pariſh in the hundred of Flitt, Bedfordſhire, England, is ſituated among ſome hills on the banks of the river Lea, three miles from Dunſtable, and 31 from London. The town is long and irregular, ſhaped ſomething like the Roman Y, the angles branching off from the market-houſe, which is an extenſive building. The population of the pariſh, according to the return in the year 1801, was 3095, inhabiting 612 houſes, which are but indifferently built. The only ſtructure in the town deſerving attention is the church, which conſiſts of a choir, a nave and two aiſles, ſupported by ten pointed arches, two tranſepts, and a handſome embattled tower at the weſt end, chequered with flint and free-ſtone; at the corners are hexangular turrets, ſimilar to that at Dunſtable. The arch of the weſt door is ornamented with mouldings of various flowers, &c. Within the church is a ſingular piece of ancient architecture, an octagonal ſtone font, incloſed in a lofty wooden frame of pointed arches, terminated with elegant tabernacle work. The conſecrated water, during the prevalence of the Roman ceremonies, was kept in a large baſon at the top, whence it was let down by the prieſt, through a pipe into the font. On the inſide of the roof a vine is repreſented, guarded by a lamb from the aſſaults of a dragon: emblematical of the defence which baptiſm affords to the church from the attempts of the devil. On the north ſide of the choir is an elegant chapel, founded by John lord Wenlock, who bore a diſtinguiſhed part in the conteſt between the houſes of York and Lancaſter. The principal manufacture carried on in Luton is that of ſtraw hats: a weekly market, noted for its abundant ſupply of corn, is held on Mondays; it is of great antiquity, being mentioned in the Domeſday Survey, where the tolls are valued at 100*s.* *per annum*: and here are two annual fairs. John Pomfret, the poet, was a native of this town: his father was firſt curate and then vicar of the pariſh.

About three miles from the town, on an elevated ſituation at the border of the Bedfordſhire downs, in the midſt of a well wooded park, ſtands Luton-Hoo houſe, the ſeat of the marquis of Bute. The old park, which conſiſted of about 300 acres, incloſed by ſir Robert Napier, was enlarged to 1200, by the late earl of Bute, and now contains about 1500 acres. The manſion was in a great meaſure rebuilt by the late earl, who employed Mr. Adam the architect. The principal rooms, particularly the library, drawing-room, and ſaloon, are on a magnificent ſcale. The library, which is 146 feet in length, is eſteemed but little inferior to that of Blenheim. The collection of pictures is very large and valuable, chiefly of the Italian and Flemiſh ſchools. The chapel is fitted up with carving in wood, which was originally executed for ſir Thomas Pope at Tittenhanger, Herts, in 1548, and removed to Luton in perfect preſervation by ſir Robert Napier. In the adjoining wood is a portico, a beautiful piece of brick building, deſigned for a manſion intended to have been built by lord Wenlock, but which was never completed: and in the park is a ſtone tower of great antiquity. Beauties of England and Wales, vol. i. Lyſons's Magna Britannia, vol. i.

LUTRA, in *Zoology*, a ſpecies of *Muſtela*. See Muſtela *Lutra*, and Otter.

LUTRY, in *Geography*, a pleaſant little town of Switzerland, in a diſtrict of the Pays de Vaud, between Lauſanne and Vevay, called "La Vaux," on the N. coaſt of the lake of Geneva; three miles E. of Lauſanne.

LUTTENBERG, a town of the duchy of Stiria, on the river Stantz; 12 miles E. of Pettau. N. lat. 46° 35'. E. long. 16° 8'.

LUTTER, a town of Weſtphalia, in the duchy of Brunſwick; 11 miles N.W. of Goſlar.

LUTTERBERG, a town of Weſtphalia, in the principality of Grubenhagen, formerly a county; 15 miles S. of Goſslar.

LUTTERHAUSEN, a town of the duchy of Holſtein; eight miles from Hamburgh.

LUTTERLOCK, a townſhip of America, in Orleans county, Vermont, N. of Craftſborough.

LUTTERWORTH, the only market town in the hundred of Guthlaxton, Leiceſterſhire, England, is ſituated on the bank of the river Swift; about two miles from the Watling-ſtreet road, 13 miles from Leiceſter, and 83 from London. Leland deſcribes this "towne as ſcant half ſo bigge as Lughborow; but in it there is an hoſpital of the foundation of two or three of the Verdounes, that were lords of auncient tyme of the towne." This hoſpital was founded, in the reign of king John, by Roiſe de Verdon and Nicholas her ſon, for a prieſt and ſix poor men, and to "keep hoſpitality for poor men travelling that way." The pariſh church of Lutterworth is a ſpacious ſtructure, with a nave, two aiſles, a chancel, and a tower with four turrets. The chancel, which is ſeparated from the nave by a beautiful ſcreen, is ſuppoſed by Burton to have been built by lord Ferrers of Groby, as his arms are cut on the outſide over the great window. By a ſtorm, in the year 1703, the ſpire, which was 50 feet higher than the preſent turrets, was blown down, and, falling on the roof of the church, did great damage to the body, pews, &c. About the year 1740, the whole was repaired, a pavement of checquered ſtone laid, and all the interior made new, except the pulpit, which is of thick oak planks, of an hexagonal ſhape, and has a ſeam of carved work in the joints; this pulpit is preſerved with great veneration, in memory of the diſtinguiſhed reformer, John Wickliffe, who was rector of this pariſh, and died ſuddenly while hearing maſs December 31ſt, 1387. The chair in which he breathed his laſt is alſo preſerved with great care; as is likewiſe another relic uſed by him, the communion cloth of purple velvet trimmed with gold. His body was buried in this church; but his doctrines having been condemned, his remains were taken up and burned, by order of the council of Sienna, in 1428, and his aſhes caſt into the river. His portrait, by S. Fielding, hangs over the gallery at the weſt end of the church. A meeting-houſe for diſſenters was built here in 1777, and is numerouſly attended. Here are alſo a ſchool-houſe and alms-houſe, built by the bequeſt of Mr. Edward Sherrier. Among other benefactions to this town, Mr. Richard Elkington, by his will, dated May 29th, 1607, left in truſt to the mayor, bailiff, and burgeſſes of Leiceſter 50*l.* to be lent in ſums of 10*l.* each to five tradeſmen of Lutterworth for one year at five *per cent.*; the intereſt to be diſtributed among certain poor perſons. In the return to the population act in 1801, this town was ſtated to contain 277 houſes and 1652 inhabitants. The cotton manufacture is carried on here to conſiderable extent; and ſome large buildings have been lately erected as factories and workſhops. Many hands are alſo employed in making ſtockings. A weekly market is held on Thurſdays, granted, with an annual fair, by king Henry V. in the ſecond year of his reign; three other fairs have ſince been obtained.

About a mile to the eaſt of Lutterworth is Miſterton Hall, the ſeat of Jacob Henry Franks, eſq. who poſſeſſes a collection of pictures. Nichols's Hiſtory of Leiceſterſhire. Beauties of England and Wales, vol. ix.

LUTUM, in *Botany*, a name given by the ancient Roman authors to a plant ſince called *luteola*, or dyer's-weed, and by authors of later date *carniola*, and *cymene*. It is uſed at this time to dye things yellow, and was ſo by the ancient Greeks, who expreſsly mention the dyeing woollen cloth with it. The Roman courtezans had alſo a way of dyeing their hair yellow with it. See RESEDA.

LUTUM *Sapientiæ* is the hermetical ſeal; made by melting the end of a glaſs veſſel by a lamp, and twiſting it up with a pair of pliers.

LUTZELSTEIN, in *Geography*. See *La* PETITE PIERRE.

LÜTZEN, a town of Saxony, in the territory of Merſeburg, with a citadel. Near this town was fought a bloody battle in 1632, between the Imperialiſts and Swedes, in which the latter loſt their king Guſtavus Adolphus; nine miles E.S.E. of Merſeburg. N. lat. 51° 16′. E. long. 12° 8′.

LUVINO, a town of Italy, in the department of the Verbano, on the E. bank of the lake Maggiore; 20 miles N.W. of Como.

LUVINO, *Valley of*, one of the five diſtricts into which the county of Bormio is divided. (See BORMIO.) The inhabitants of the Luvino poſſeſſed certain privileges, particularly the power of judging civil cauſes within a certain value; but they did not appoint any of the magiſtrates, who were all choſen from the other four diſtricts.

LUVIO, a town of Sweden, in the government of Abo; nine miles S.S.W. of Biorneborg.

LUXATION, or DISLOCATION, in *Surgery*, denotes any caſe where the articular extremities of bones abandon their natural relations, whether the head of a bone eſcapes from a cavity deſtined for its reception, or whether the ſurfaces of the joint ceaſe to correſpond properly one to the other. A luxation is termed *complete*, when the ſurfaces of the joint are totally ſeparated; *incomplete*, when they remain partially in contact, though in a ſtate of diſplacement, with reſpect to each other. Like fractures, diſlocations are alſo divided into *ſimple* and *compound*; ſimple, when there is no external wound communicating with the joint; compound, when the caſe is conjoined with ſuch an accident.

Other general differences of luxations depend upon the articulation in which they take place; the direction in which the bone is diſplaced; the length of time the accident has continued; and the cauſe that has produced it.

The greater the extent and variety of motion of joints, the more ſubject they are in general to be diſlocated. Thus, the orbicular articulations, ſuch as that of the humerus with the ſcapula, are thoſe in which luxations are moſt frequent. In the ginglimoidal articulations, on the contrary, which admit only of motion in two oppoſite directions, the accident is far leſs common; and in ſuch joints as only allow a ſlight yielding motion of the bones on each other, a diſlocation ſtill more rarely occurs. The frequency of luxation, however, in the orbicular articulations, and the comparative unfrequency of them in the ginglimoidal, as Boyer rightly obſerves, may be explained from many circumſtances, independent of the quantity and variety of motion which ſuch joints admit of. In the ginglimoidal, the bony ſurfaces, which come into contact, and are adapted to one another, are of conſiderable extent; the ligaments which bind them together are very numerous and ſtrong; and the muſcles are ſo arranged, as to have a ſhare in ſtrengthening ſuch articulations.

We have mentioned, that luxations are diſtinguiſhed into *complete* and *incomplete*, the latter term being uſed, when the ſurfaces of the joint are yet partially in contact, though diſplaced and not exactly correſponding. Incomplete luxations only happen in the ginglimoidal articulations, as thoſe of the foot, the knee, and the elbow. In theſe joints, indeed, the diſlocation is almoſt always incomplete; as it could only be made complete by the operation of a vaſt force. With reſpect to the orbicular joints, it is very different, as few of them are ſubject to any diſlocation, that is not complete. If the head of the humerus, or thigh-bone, is forced on the cartilaginous brim, ſurrounding the cavity deſtined for its reception, the round ſlippery ball only touches the part on which it reſts by a few points, and, therefore, either re-enters its natural ſocket again, or ſlips entirely from it; in the latter event, of courſe the luxation is complete.

But as M. Boyer has noticed, there are ſome articulations which, though truly orbicular, are yet liable to incomplete luxations. For inſtance, the head of the aſtragalus may be ſo diſplaced, as only to abandon, in a partial manner, the cavity in the poſterior ſurface of the os naviculare. However, in this example, the orbicular ligament is tight, very ſtrong, and the motion inconſiderable. Laſtly, it may be obſerved, with regard to the extent of diſlocations, that when the head of a bone is entirely thrown out of the cavity, in which it is naturally placed, it may be forced to a greater or leſs diſtance between the interſtices of the muſcles.

On the ſubject of the different directions, in which a bone may be diſplaced, we have to ſtate, that, in the round articulations, it may be luxated in the direction of all the radii, which paſs from the centre of the circle formed by the circumference of the articular cavity. In fact, there is not a point of the edge of the glenoid cavity where the humerus may not eſcape. However, owing to particular circumſtances of conformation, a luxation moſtly takes place in certain directions, well aſcertained by experience, ſo that the varieties of diſlocations, diſtinguiſhed by the courſe of the diſplaced bone, are, as Boyer well explains, much leſs numerous than might at firſt be ſuppoſed. The terms *upwards, downwards, forwards, backwards, inwards*, and *outwards*, are frequently applied to luxations, as denoting the direction in which the head of a bone is diſplaced. Ginglimoid joints are generally ſuſceptible of being diſlocated only in the direction of two lines, namely, a tranſverſe one, and one extending from the front to the back of the articulation.

The length of time a diſlocation has exiſted makes a difference of the higheſt importance, the difficulty of cure increaſing in proportion to the time the accident has been left unreduced; and, indeed, after a certain time, the reduction becomes impracticable.

The ſoft parts and the bone itſelf have acquired a certain poſition, and the ligaments and muſcles ſurrounding the diſeaſed joint become ſtiff, and yield with difficulty to the efforts made to reduce the bone. If a certain number of days have elapſed, the laceration in the ligaments may have become ſo far cloſed as to render the reduction impoſſible. Laſtly, the head of the bone may have become firmly adherent to the parts, amongſt which it has been forced.

Luxations, in general, may be complicated with a greater or leſs degree of contuſion, with a wound or fracture, with a rupture of a blood-veſſel and conſequent effuſion of blood in the cellular ſubſtance, with contuſion of an important nerve, and a paralyſis of the organs to which it is diſtributed, &c.

The following general account of the cauſes, ſymptoms, prognoſis, and treatment of luxations, is chiefly from Boyer's lectures on the diſeaſes of the bones.

The cauſes are divided into external and internal; both are prediſpoſing or occaſional.

The prediſpoſition to luxation may depend on circumſtances natural or accidental. The natural are, the joint admitting of great latitude of motion, the ſmall extent of ſurfaces by which the bones are in contact, the laxity and ſmall number of the ligaments uniting them, the weakneſs of one ſide of an articulation ariſing, for inſtance, from a great notch on one ſide, as is obſerved at the interior and inferior part of the acetabulum, diſeaſe, ſuch as a paralyſis of the muſcles, which ſurround an articulation, and a weakneſs and relaxation of its ligaments, may alſo occaſion a prediſpoſition to diſlocations. In a paralyſis of the deltoid muſcle, the weight of the arm alone has been known to produce an elongation and gradual relaxation of the capſular ligament of the ſhoulder joint, and to remove the head of the humerus two or three inches from the glenoid cavity of the ſcapula. Boyer has obſerved in a child that laboured under an atrophia of the muſcles of the arm, an empty ſpace of nearly an inch between the head of the bone and the ſurface of the glenoid cavity, which could be diſtinctly felt through the emaciated deltoid muſcle.

Sometimes the relaxation of the ligaments appears without any evident cauſe, and gives ſuch a diſpoſition to luxations, that they take place from the ſlighteſt cauſes; ſuch was the caſe of a woman who could not yawn even moderately, without luxating the lower jaw. It may not be amiſs to obſerve that theſe luxations, depending on exceſſive looſeneſs of the ligaments, are, by reaſon of ſuch looſeneſs, in general very eaſily reduced. A diſeaſed ſtate of joints may alſo diſpoſe to luxations, by deſtroying the ligaments and articular ſurfaces. What ſurgeon of any experience at all has not frequently ſeen examples in which the head of the thigh-bone has been diſlocated, in conſequence of diſeaſe in the hip? Even the knee, which is a ginglimoidal joint, ſometimes becomes partially luxated in caſes of white ſwelling.

In order that external violence, a blow, a fall, or even the action of the muſcles, produce luxation in a ball and ſocket articulation, the axis of the bone muſt be placed in a direction, more or leſs oblique, with reſpect to the ſurface with which it is articulated. If, for example, the os humeri hangs exactly along the ſide of the body, or perpendicularly with reſpect to the glenoid cavity of the ſcapula, no force can produce a luxation. If a perſon falls on the elbow, while the fore-arm is in this poſition, the head of the humerus will be forced againſt the cavity formed for its reception; but if the arm is lifted more or leſs from the body, the axis of the humerus will fall obliquely on the ſurface of the glenoid cavity, and the eſcape of the head of the bone from ſuch cavity will be facilitated. This tendency to a diſlocation will be increaſed in proportion as the angle formed by the axis of the bone with the ſurface of the glenoid cavity deviates from a right angle. In the ginglimoidal articulations luxations may be cauſed by a fall, or other kinds of external violence, and they are moſtly incomplete. In the orbicular joints the action of the muſcles has conſtantly a ſhare in the production of the accident. Thus, for inſtance, if a perſon falls on the elbow, whilſt the arm is raiſed from the body, and carried directly outwards, the ſhock which this part receives will certainly tend very much to force the head of the humerus out of the glenoid cavity on the lower and internal ſide; but the action of the pectoralis major, latiſſimus dorſi, and teres major, contributes alſo very much to throw the bone out of its place. In fact the elbow, reſting on the ground, becomes the fulcrum, or centre of motion of the humerus; in this ſtate, we obey a mechanical inſtinct, which leads us ſuddenly to bring the arm cloſe to the body, and as the reſiſtance made by the ground prevents this, the violent and inſtantaneous contraction of the pectoralis major, latiſſimus dorſi, and teres major, draws downwards and inwards the head of the humerus; the luxation being thus partly the effect of the fall, and partly the effect of ſuch muſcular action. Whatever may be the manner in which the cauſes act, luxations are always accompanied with more or leſs laceration of the ligaments, and injury of the other ſoft parts about the joint; and in the orbicular articulations, like thoſe of the ſhoulder and hip, the capſular ligaments are always torn.

With reſpect to the general ſymptoms of luxations we need not dwell much upon pain and inability of moving the limb, as, at moſt, they are only equivocal, and common to diſlocations, fractures, and ſimple bruiſes. They are not, however, to be entirely overlooked, but ſtill in forming a diagnoſis we ſhould endeavour to found it on the exiſtence of ſymptoms manifeſt to the ſenſes, ſuch as an elongation or ſhortening of the limb; a change in its ſhape and direction; and laſtly, the abſolute impoſſibility of performing certain motions.

A luxation cannot poſſibly exiſt, unleſs the affected limb is either lengthened, as happens in the lower extremity, when the head of the femur paſſes out of the acetabulum, in the direction downwards and inwards, and reſts on the foramen ovale; or ſhortened, as takes place when the ſame bone is luxated upwards and backwards, and has its head thrown towards the external depreſſion in the ilium. But it is to be remarked, that the ſhortening and elongation are rarely produced, except by luxations of orbicular joints. However, the abſence of theſe ſymptoms in diſlocations of the ginglimoidal articulations is amply compenſated by the ſuperficial ſituation of the bone; a circumſtance which renders it eaſy to aſcertain their relative poſitions.

The direction of the bone is changed, for the luxated end cannot leave its natural place, without the other being thrown into a contrary direction. Thus, in the luxation of the humerus downwards and inwards, the poſition of the arm is obliquely downwards and outwards, inſtead of being ſtraight along the ſide. This mode of judging of the occurrence of a diſlocation by the change in the direction of the limb, is much eaſier in recent caſes, than in thoſe which have continued for a conſiderable time.

As the ſituation and direction of a diſlocated bone are altered, it neceſſarily follows that ſome muſcles muſt be preternaturally relaxed, while others are overſtretched and ſtrained, as may be ſeen with reſpect to the deltoid muſcle, in caſes of luxations of the humerus, which are the moſt frequent of all. This unequal tenſion and relaxation of muſcles may alſo afford ſome aſſiſtance in forming the diagnoſis.

Time ſeems, however, ſomething to remove, in a great meaſure, the alteration produced in the contour of a limb, by certain luxations; and it is obſerved that in old diſlocations of the humerus, the fulneſs of the ſhoulder, juſt below the acromion, is in ſome degree reſtored.

In theſe alterations of the natural ſhape of the limbs, we are to comprehend the changed relations of the eminences of a joint with reſpect to each other; the exiſtence of projections in places, where there ought to be depreſſions; and of depreſſions where there ought to be eminences. Thus, in the luxation of the humerus inwards and downwards, a hard tumour cauſed by the head of the bone itſelf, may be diſtinctly felt in the hollow of the axilla, while an unnatural depreſſion may be perceived juſt under the acromion.

Our limbs, even when fractured, as Boyer has obſerved, may be made to perform ſeveral motions, and may be put into various attitudes. In a caſe of a broken thigh, the ſurgeon (not, in truth, without cauſing ſevere pain,) may, by taking hold of the leg, move it round in a circular direction, and may point the foot inwards and outwards. But in luxations of the thigh, ſuch motions are altogether impoſſible, before the bone is reduced.

By a conſideration of all theſe ſymptoms, diſlocations may always be detected. When the caſe is not aſcertained within a moderate time, either through negligence or ignorance, it is a ſerious affair for the patient; becauſe the inability of uſing the limb is imputed to the contuſion, and the treatment is regulated accordingly; the bone, after a time, becomes incapable of reduction, and the lameneſs and deformity are then irremediable. Such ſurgeons as are groſsly deficient in anatomical knowledge, are the moſt liable to deliver wrong opinions concerning diſlocations; for, not being able to judge of the due relative diſtances which ought to exiſt between certain proceſſes of the bones, they are not at all qualified to decide whether many caſes are mere contuſions, or whether they are fractures or diſlocations.

On the ſubject of prognoſis in caſes of diſlocation, it is remarked that luxations of the orbicular joints are much leſs dangerous than thoſe of the ginglimoidal articulations. As the action of the muſcles has a great ſhare in producing the firſt deſcription of caſes, there is leſs violence done to the external parts, and the ſoft parts are leſs lacerated.

In all caſes the extent of the evil is in proportion to the largeneſs of the ſurfaces of the joint, the number and ſtrength of the ſurrounding muſcles, and the thickneſs and number of the ligaments. Hence, luxations of the foot and knee are more dangerous than thoſe of the elbow and wriſt; the former require a much greater degree of external violence to produce them, and conſequently the ſoft parts are more injured.

Luxations of the orbicular joints are more difficult of reduction than thoſe of the ginglimoidal articulations, and diſlocations of the hip are more troubleſome to reduce than luxations of the ſhoulder. Theſe circumſtances are explicable by the power and action of the muſcles, in reſiſting the endeavours of the ſurgeon to bring the head of the bone into its place again.

But, perhaps, the thing which, of all others, tends moſt to increaſe the danger of a diſlocation, is the accident being, what is termed *compound*, that is, attended with an external wound, communicating with the cavity of the luxated joint. Many ſuch caſes require immediate amputation. The propriety of the operation depends, however, in a great meaſure on the extent of injury done to the ſoft parts. When theſe have not been largely lacerated, torn, and contuſed, the ſurgeon ſhould endeavour to ſave the limb. Even the hazard of a compound diſlocation very much depends on the kind of joint affected. Such injuries of the articulations of the fingers or toes cannot be compared, in point of danger, with ſimilar accidents intereſting the ankle, the knee, or the elbow.

Luxations ariſing from diſeaſe of a joint, cannot in general be reduced and cured like diſlocations from external violence; for the ligaments and articular ſurfaces are, in fact, always more or leſs deſtroyed. This obſervation, however, is not to be extended to luxations, induced by a mere looſeneſs of the ligaments. Theſe caſes indeed are very ſubject to recur; but they can eaſily be reduced. Many diſlocations of the jaw are connected with a lax ſtate of the ligaments, and afford an illuſtration of the preceding remark.

Laſtly, the danger of diſlocations in general is much influenced by the degree of contuſion preſent, and by the injury done to blood-veſſels, or large nerves. The latter violence ſometimes occaſions a paralyſis of the muſcles, to which the injured nerves ſends its filaments. Boyer has ſeen a paralyſis of the deltoid muſcle brought on by a violent contuſion of the circumflex nerve, in a luxation of the humerus downwards and inwards.

We have now to conſider the general treatment of luxations.

To reduce the diſlocated bone, keep it in its place, and prevent or remove the ſymptoms with which the luxation may be complicated, form the three indications which are to be fulfilled in the treatment of luxations. The reduction is accompliſhed, as in caſes of fracture, by three means, oppoſite in their action, but tending to the ſame end, *viz.* extenſion, counter-extenſion, and coaptation.

In the article Fracture we have expatiated a good deal on relaxing the muſcles connected with the broken bone, in order to facilitate the reduction of the fracture. This great principle, which was ſo much and ſo juſtly urged by Mr. Pott, holds equally good in caſes of diſlocation. From the action of the muſcles principally ariſe all the trouble and difficulty which attend the reduction of luxated joints. The mere bones, compoſing the articulations, or the mere connecting ligaments, would in general afford very little oppoſition. It is the muſcles that chiefly oppoſe the reduction, and their reſiſtance muſt either be eluded or overcome; terms, ſays Mr. Pott, of very different import, and which every practitioner ought to be well apprized of. We ſcarcely need add, that this eminent ſurgeon was a ſtrong advocate for relaxing the muſcles belonging to the diſlocated joint, at the time of attempting to reduce the bone. Now, although this precept is, generally ſpeaking, moſt excellent as far as it is practicable; we are not to run away with the idea that things are preciſely as Mr. Pott has repreſented them to be, in his general remarks on fractures and diſlocation. No ſurgeon, of the preſent time, is ſo abſurd as to imagine that merely bending the elbow, or the knee, will relax all the muſcles which have the power of reſiſting the reduction of a diſlocated ſhoulder or hip. Neither will the moſt advantageous poſition for extenſion always allow the poſture to be entirely regulated with a view towards the relaxation of the muſcles. While, however, we profeſs theſe ſentiments, we feel a thorough conviction that attending to the relaxation of ſuch muſcles as have the greateſt power of oppoſing the reduction of a diſlocation, is an unobjectionable maxim, as far as it can be received in actual practice, conſiſtently with ſome other equally important objects. When Mr. Pott wrote ſo ſtrenuouſly in favour of relaxing the muſcles, or, as we ſhould rather ſay, of bending joints, in caſes of diſlocation, it was alſo neceſſary for him to lay much ſtreſs on the advantage of applying the extenſion to the end of the diſlocated bone itſelf; becauſe, were it applied in a better ſituation, the bent poſition would become inadmiſſible. The reaſon which is aſſigned for this practice, however, is, as might be expected, moſt weak. Mr. Pott talks a great deal about the *dilatability*, or *diſtractile power* of the ligaments, and their capacity of giving way when ſtretched or pulled, much more, we think, than facts juſtify, ſince it is the general nature of ligaments, we mean ſuch as actually hold the bones together, to be very ſtrong and unyielding. The capſular ligaments, we think, are generally to be regarded rather as bags for the ſynovia, than as a means of ſtrengthening the articulations. The yielding nature of ſuch ligaments, therefore, can have little to do with the ſubject of diſlocations. Now it appears to us that Mr. Pott was anxious to make the ligaments appear more elaſtic than they really are, in order that he might repreſent all the extending force applied to the bone below the diſlocated one, as being loſt in the intervening unluxated articulation. Even were the ligaments of the knee, for inſtance, to yield in the manner inſinuated by Pott, when the extenſion is applied to the lower part of the leg, the extending force would ſtill not be loſt, but would operate with full effect on the thigh. Where is it loſt? The very circumſtance of the ligaments being on the ſtretch, proves that the force operates on them, and they being attached to the os femoris, this bone cannot fail to receive the extenſion in a degree preciſely equal to that with which the ligaments themſelves receive it. It is extraordinary that reaſoning ſo abſurd ſhould have impoſed upon the generality of ſurgeons in this country; eſpecially as on the continent, its falſity has long ſince been expoſed in the writings of Fabre, Dupony, Deſault, Boyer, and Richerand. The doctrine of Pott is the moſt ancient; but the antiquity of any practice ſhould ceaſe to be a reaſon for a perſeverance in it, the moment the principles, on which it is founded, are proved to be erroneous.

We differ then from Pott, and believe with the moſt conſummate ſurgeons on the continent, that the extending force ſhould be applied, not on the luxated bone, but on that with which it is articulated, and as far as poſſible from it.

All the ancient authors, as Boyer remarks, adviſed applying the extending force on the luxated bone, for inſtance applying it above the knee in luxations of the thigh-bone, and above the elbow in thoſe of the humerus. Many of the moderns have followed their inſtructions; and this mode is found recommended by J. L. Petit and Duverney in their treatiſes on the diſeaſes of the bones. Two members of the Academy of Surgery in France, Fabre and Dupony, ſaw the inconvenience of this practice, and ſubſtituted for it a mode of treatment now generally adopted on the continent. Their practice, which conſiſts in applying the extending force to the bone that articulates with the luxated one, has two moſt important advantages; firſt, the muſcles which ſurround the luxated bone are not compreſſed nor ſtimulated to ſpaſmodic contractions, which would prevent the reduction, not only by oppoſing a force ſuperior to that employed for the purpoſe of reduction, but alſo by retaining the head of the bone engaged in the interſtices of the contracted muſcles. Secondly, the extending force is much more conſiderable than it is in the other method, for, as Dupony has obſerved, by elongating thus the arm of the lever, we acquire a degree of power which the difficulties preſented in a great number of caſes force us to have recourſe to. It is true, ſays Boyer, an apprehenſion has prevailed that the extending force applied at a diſtance from the luxated bone, would loſe in the articulations of the limb a part of its effect. Thus it has been alleged, that a part of the extending force applied at the wriſt, in a luxation of the humerus, is employed in elongating the ligaments of the elbow joint. But this objection is ill founded; all the muſcles which go from the humerus to the bones of the fore-arm, by ſtrengthening the elbow, make it anſwer as a continued lever, along which the force is communicated without any loſs.

Force, applied by the hands of intelligent and ſtrong aſſiſtants, is generally conſidered preferable to any mechanical means in the reduction of diſlocations. The number of aſſiſtants may be increaſed at will, and force proportioned to the reſiſtance that is experienced. Should there not be room for a ſufficient number to take hold of the limb, they may make the extenſion by means of a napkin, or ſheet, folded longitudinally and tied on the limb. It is ſaid that the force employed can be better judged of when the extenſion is made by a certain number of aſſiſtants, than when a multiplied pulley is uſed, which may act with ſuch force, without our being aware that the muſcles, ligaments, and even the ſkin which covers the articulation, may be lacerated, and the moſt direful ſufferings occaſioned.

Although the writer of this article fully aſſents to the general ſuperiority of making the extenſion by the aſſiſtants, he cannot refrain from expreſſing a favourable opinion of the convenience and efficiency of a pulley, in caſes where *intelligent* aſſiſtants are not at hand, and where much force is required for the reduction, as, for inſtance, when the thigh-bone, or humerus, has been out of its place ſome time, or when the patient is very muſcular and ſtrong. At the ſame time, the dangerous conſequences which may happen, when a rough, unſkilful, or impatient practitioner dares to employ a pulley, cannot be too deeply impreſſed upon a ſurgeon's mind. Whether extenſion is made in the ordinary way, or with a pulley, it ſhould be made with moderation, as the muſcles are more ſure of being ſafely overcome by length of reſiſtance than by the exertion of violence.

It is impoſſible to aſſign the preciſe degree of force to be employed; it is to be varied and proportioned, according to the ſtrength of the patient, and the number and force of the muſcles ſurrounding the articulation. It has been ſaid, that, in reducing a luxation, there is occaſion for more addreſs than force; it would be true, obſerves Boyer, to ſay, that the union of both is neceſſary. Often ſix aſſiſtants accompliſh that which three cannot do, and nine or ten perform that which cannot be done by ſix.

With regard to the direction in which the extenſion ſhould be made, Boyer recommends it to be at firſt the ſame as that which the luxation has given the diſlocated bone. Suppoſe the head of the humerus to be luxated inwards, and forced into the foſſa ſubſcapularis, between the ſubſcapularis muſcle and the ſcapula: in this caſe, the elbow is not only moved out from the trunk, but even carried backwards. Now, if we were to commence the reduction, by pulling in the natural direction of the humerus, that is, directly outwards, the head of the bone would be preſſed againſt the foſſa ſubſcapularis, it would not eaſily ſlide along, the force would be ſpent in puſhing the ſcapula backwards, and the irritation would excite the contraction of the muſcles ſituated near the luxated head of the bone.

Extenſion, then, is generally to be made at firſt in the direction which the luxated bone has taken; but in proportion as the muſcles become elongated, and yield to the force acting on them, the bone is to be gradually brought back into its natural poſition. In this manner the head of the bone is diſengaged from the parts in which it has been placed, and is brought back to the cavity which it has left, by making it deſcribe the ſame courſe that it took in making its eſcape.

We are now to conſider what is termed *counter-extenſion.*

As Boyer has juſtly remarked, the beſt directed extenſion will be uſeleſs, if the bone with which the luxated one has been articulated, is not kept motionleſs by counter-extenſion, a force equal to the other, but made in a contrary direction. The counter-extending power, applied to the luxated bone itſelf, would be attended, in almoſt every caſe, with the double inconvenience of producing a ſpaſmodic contraction of the muſcles, and preventing the elongation of them neceſſary for reduction. Let us ſuppoſe, ſays Boyer, that in a luxation of the thigh, the counter-extending bandage were in the fold of the groin of the affected ſide, the conſequence would be, that the triceps and gracilis, which are in a ſtate of tenſion between the pelvis and thigh, would be puſhed inwards, and, conſequently, ſhortened, when their elongation is abſolutely neceſſary. Beſides, the compreſſion made on them would alſo increaſe their contraction. The counter-extending force ought, therefore, to be applied immediately above the luxated bone. Sometimes the counter-extenſion is made by aſſiſtants, who take hold of the bandage neceſſary for the purpoſe; ſometimes it is executed by faſtening the bandage to a fixed point. The latter mode, when practicable, is to be preferred. The counter-extenſion ſhould always be made in a perpendicular direction with reſpect to the ſurface of the luxated joint. In a luxation of the elbow, for inſtance, the counter-extenſion ſhould be made in a line parallel to the os humeri; and in a diſlocation of the thigh-bone, the counter-extenſion, applied to the pelvis, ſhould be made perpendicularly to the ſurface of the acetabulum. The ſame rule is to be obſerved with regard to the ſhoulder in luxations of the humerus.

In general, when the extenſion is ſufficient, coaptation is eaſily performed. In a luxation of the humerus, as the head of the bone is diſengaged, and the aſſiſtants have brought the bone into its natural direction, the ſurgeon is to ſeize the opportunity, and with one hand preſs on the ſuperior and inner part of the arm, whilſt, at the ſame time, he ſupports the elbow with the other, and thus conducts the head of the bone into the glenoid cavity.

It is an excellent maxim, whenever practicable, to uſe a diſlocated bone as a ſort of lever, in making the reduction. Thus, after the head of the humerus has been diſengaged by the extenſion, if, while preſſure is made at the upper and inner part of the arm, the elbow is depreſſed, the head of the bone moves upwards in proportion towards the glenoid cavity of the ſcapula. The recollection of this principle will materially aid in reducing diſlocations of the jaw, thigh-bone, &c. Common ſenſe points out, in almoſt every caſe, how and where the fulcrum ſhould be made.

Luxations of ginglimoidal articulations being ſeldom complete, the extenſion and counter-extenſion are generally made, in ſuch inſtances, only with a view of diminiſhing the friction of the ſurfaces of the joint, neceſſarily occaſioned by the oppoſite motions given them, with a view of replacing them in their natural ſituation.

When extraordinary difficulty is encountered in reducing a diſlocation, the ſurgeon ſhould endeavour to aſcertain the cauſe. Sometimes want of ſucceſs is owing to the inſufficiency of the means employed, in which circumſtance, we muſt either increaſe the extending power, or diminiſh the muſcular force of the patient.

The latter object may be fulfilled in various ways. Change of poſture often produces the effect. In Boyer's work inſtances are mentioned in which patients, while ſeated on a chair, and ſupporting themſelves with their feet againſt the ground, could not have their luxations reduced with the greateſt efforts; and yet afterwards had their diſlocations reduced with unexpected facility, on being laid horizontally on a long fixed table, where their muſcles were deprived of a centre of motion. In general, however, the benefits of poſture may, with more reaſon, be imputed to its relaxing the moſt powerful muſcles oppoſing the endeavours of the ſurgeon.

When every attempt, conducted on the foregoing principles, proves ineffectual, the patient is to be largely and repeatedly bled, be put into the warm bath, and confined to a very low diet. As ſoon as he appears to be conſiderably weakened by this plan, the diſlocation, which was previouſly irreducible, may frequently be reduced with the utmoſt eaſe. We do not coincide with Boyer, when he adviſes us to loſe twenty-four hours in lowering the patient, before renewing the attempts at reduction. On the contrary, ſo fully are we convinced of the difficulty of reduction, always proceeding from delay, that we earneſtly recommend the efforts to reduce the bone to be renewed immediately after the patient has been weakened by the firſt copious bleeding, and to be tried again as ſoon as he has been a certain time in the bath. The faintneſs and debility following ſuch means, afford the moſt favourable opportunity for reducing a diſlocation. The ſtate of intoxication, induced by ſpirits or opium, is alſo well known to facilitate the reduction of luxated bones, by incapacitating the muſcles to make reſiſtance, and putting them into a condition in which they yield and become elongated by a very moderate force. Thus Boyer, by himſelf, and at the firſt attempt, reduced a luxation of the arm of an intoxicated poſtillion, while the aſſiſtants were preparing the apparatus for the reduction. The plan of purpoſely intoxicating patients, whoſe diſlocations cannot be reduced by ordinary means, has even received the recommendations of ſome ſurgical authors.

But, perhaps, of all the plans propoſed for overcoming the reſiſtance of the muſcles to the reduction of diſlocations, fatiguing thoſe organs by long continued unremitting extenſion is, when combined with due attention to the choice of ſuch a poſition as will relax the moſt powerful ones, the moſt effectual that can be adopted. The ſtrongeſt muſcles may always be overcome by keeping up, for a certain time, even a very moderate degree of extenſion. The thing is not to remit or diſcontinue for a moment the operation of the extending power. This principle is ſaid to have been firſt applied to practice by Lebat, who, in a caſe where the levatores of the lower jaw were ſpaſmodically contracted, in a diſlocation of that bone, and would not allow the part to be brought down, introduced a ſmall ſtick between the teeth, and making uſe of it as a lever, oppoſed the action of the muſcles until they were incapable of further reſiſtance, and the reduction was accompliſhed. M. David is alſo ſtated to have derived ſimilar advantages from the ſame practice, in luxations of the thigh and arm.

When luxations have been left unreduced ſeveral days, the reduction frequently becomes exceedingly difficult, and ſometimes quite impracticable. The lacerated opening in the capſular ligament, after a time, becomes cloſed, and thus a material impediment to the reduction is occaſioned. When a diſlocation has exiſted for weeks and months, many circumſtances take place to prevent the poſſibility of reduction: the head of the bone acquires connections in its new and unnatural ſituation; the muſcles become incapable of ſufficient elongation again; and, what is worſe, the articular cavity ſuffers more or leſs obliteration. In the ginglimoidal joints, an anchyloſis is ſoon produced, and the reduction rendered impracticable. We have ſeen many attempts made with multiplied pullies to reduce old diſlocations. In a few inſtances, a degree of benefit was thought to have been the reſult; but in no inſtance was the ſucceſs complete. Theſe luxations, however, might have exiſted an unreaſonable length of time. It is difficult to pronounce exactly how long a diſlocation of the arm or thigh muſt have happened, to juſtify the abandonment of all attempts at reduction. The celebrated French ſurgeon Deſault ſucceeded by the prudent employment of force in reducing many caſes which had exiſted for ſeveral months; and ſuch facts call upon the practitioner not to give up at once every old diſlocation as paſt relief. A patient's means of ſubſiſtence, for himſelf and his family, will often entirely depend upon his luxation being reduced. In the ginglimoidal joints, as we have already obſerved, luxations ſooner become irreducible: according to Boyer, after twenty, or four-and-twenty days, they, in general, cannot be replaced, owing to an anchyloſis having occurred.

The ſurgeon knows, that a luxation is reduced by the limb having recovered its natural length, ſhape, and direction, and by its having regained the power of performing certain motions impoſſible during the diſlocation. For ſome time after the reduction the limb ſhould not be moved, except with the utmoſt caution: a recurrence of a diſlocated ſhoulder has been known to ariſe from carrying the hand inadvertently to the forehead, by a ſemicircular motion.

The ceſſation of pain has been conſidered as a ſign of the reduction being effected; but, as Boyer has juſtly remarked, by ceſſation, we are to underſtand a conſiderable diminution, rather than a total diſcontinuance of pain.

Laſtly; one of the moſt unequivocal and ſatisfactory indications of the reduction being accompliſhed, is the particular noiſe made by the head of the bone when it ſlips into the articular cavity again.

After a diſlocation has been reduced, the grand object that now preſents itſelf, is to keep the joint motionleſs, ſo as to hinder a relapſe, and give the torn ligaments an opportunity of growing together again. All motion of the limb is, therefore, to be prevented. As the humerus cannot be luxated, except when it is at ſome diſtance from the body, a return of its diſlocation will be effectually prevented by tying the elbow to the ſide of the body. The bandage employed for keeping the limb motionleſs, ſhould always be made to operate principally on the end of the bone moſt remote from the joint affected. Thus, after a luxation of the arm, when we apply to the elbow the means for keeping the bone in its place, we act on that point of the humerus the moſt diſtant from its articulation with the ſcapula, and the force thus applied to the extremity of the lever, acts with much more effect. The ſame rule ſhould be obſerved in the application of a bandage to the chin, after a luxation of the jaw. Indeed, in this laſt caſe, ſuch practice has been recommended by all ſurgical writers; but in diſlocations of the ſhoulder and hip, they ſeem to have forgot the utility of the principle, and have generally adviſed that moſt inert bandage termed the ſpica, which only acts on the centre of motion, and, conſequently, can have little or no effect in keeping the bone fixed.

When a luxation ariſes from an internal cauſe, ſuch as paralyſis of the muſcles, a looſeneſs of the ligaments, or general debility, the duty of the ſurgeon is to endeavour to obviate the cauſe by ſuitable remedies, as well as replace the bone. We confeſs, however, that we know of no medicine nor application that ſeems to be calculated to remove a lax ſtate of the ligaments.

Luxations, in general, are particularly liable to be accompanied by more or leſs contuſion of the ſoft parts; and they are ſometimes complicated with inflammation, rupture of blood-veſſels, injury of nerves, and even a fracture. The latter complication is not frequent, but when it does occur, the bone has always been luxated firſt, and afterwards broken by the violence. The paralyſis ariſing from a contuſion of the nerves is not an uncommon conſequence of diſlocation of the ſhoulder; and when we conſider the relation between the head of the humerus and the brachial plexus, the occurrence is by no means ſurpriſing.

Boyer obſerves, that when a luxated bone is not reduced, ſometimes it remains in the place into which it has been forced; but much more frequently it changes its ſituation, and is carried ſtill further from the cavity of the joint by the action of the muſcles. Thus, in luxations of the thigh upwards and outwards, the glutei muſcles continue to draw the head of the thigh-bone up along the dorſum of the ilium, until the limb is ſhortened as much as the parts will allow.

But, as the ſame ſurgeon has explained, whether the head of the luxated bone preſerves its firſt poſition, or takes another, it becomes flattened on that ſurface, by which it is in contact with a ſubjacent bone, while this laſt has a kind of depreſſion gradually made in it. In ſome inſtances the original cavity of the joint diminiſhes in depth, eſpecially when the head of the bone remains near its circumference. The muſcles, impeded in their action, loſe their conſiſtence, aſſume a ligamentous appearance, and even become attached to the ligaments by a depoſition of oſſeous matter, and, in this manner, a bony caſe is formed, which conſtitutes, with the diſplaced bone, a new articulation.

When a bone is not reduced, the limb remains deformed, and ſcarcely any uſe can be made of it for ſome months; but in time it approaches rather more to its natural direction, and when a new joint is formed, is yet capable of a conſiderable latitude of motion. In general, however, in conſequence of the motion of the limb being more or leſs obſtructed, the muſcles fall away, and the limb has a weak and leſs bulky appearance than that of its fellow. When a diſlocation in a child is left unreduced, this difference between the ſize of the luxated limb and that of the ſound one, becomes very remarkable as the patient grows up to the adult ſtate.

We ſhall now treat of particular diſlocations, and afterwards conclude with ſome obſervations on compound luxations.

Luxations of the lower Jaw-bone.—When the mouth is widely opened, the condyles of the lower jaw advance forwards upon the eminentiæ articulares, and in this ſtate may be made to ſlip under the zygomatic proceſſes by very ſlight cauſes. This bone is only liable to be luxated in this one direction, whether one or both condyles eſcape from the glenoid cavities of the temporal bones. Every luxation, except that forwards, is rendered impoſſible by the natural conformation of the parts. A diſlocation backwards is oppoſed by the oſſeous portion of the auditory canal; and luxations laterally, to the right or left, are prevented by the reſiſtance ariſing from the ſpinous proceſſes of the ſphenoid bone and the ligaments of the joint. But it muſt be confeſſed, that the principal ſtrength of the articulation of the lower jaw does not depend upon theſe ligaments; but rather on the muſcles, and the particular conformation of the bones. The very ſhape of the lower jaw at once informs us, that a blow on its ſides muſt be more likely to break it, by increaſing its curvature, than diſlocate it.

According to Boyer, luxations of the lower jaw cannot happen in very young infants, on account of the body and rami of this bone meeting at an obtuſe angle, and, conſequently, the condyles and necks having nearly the ſame direction as the reſt of the bone, ſo that a luxation cannot be cauſed by any poſſible depreſſion of the chin. Diſlocations of the jaw are ſeldom cauſed by external violence; almoſt always by exceſſive yawning, or laughing.

The condyles of the maxilla inferior, being thrown before the tranſverſe roots of the zygomatic proceſſes, compreſs the deep-ſeated temporal nerves, and thoſe going to the maſſeters. This fact affords a better explanation of the pains attending a luxation of the jaw, than the tenſion and elongation of the maſſeter and other muſcles.

Beſides great pain, a more inſtructive ſymptom of this accident is the mouth being much open, and incapable of being ſhut. Theſe circumſtances are more evident in recent than old luxations of the jaw. An empty ſpace may be felt before the ears in the natural ſituation of the condyles. The coronoid proceſs forms under the cheek bone an eminence, which is perceptible through the cheek, or by introducing a finger into the mouth. The cheeks and temples are flattened by the lengthening of the temporal, maſſeter, and buccinator muſcles. The ſaliva flows in large quantities from the mouth, the ſecretion being augmented in conſequence of the exiſting irritation. The arch formed by the teeth of the lower jaw is placed anteriorly to that made by thoſe of the upper jaw. Laſtly; during the firſt days of the luxation, the patient can neither ſpeak nor ſwallow.

We have already adverted to one condyle being ſometimes diſlocated, while the other remains in its proper place. According to Mr. Hey, it is not always eaſy to know when this is the caſe. "One would expect," ſays this practical writer, "from a conſideration of the ſtructure of the parts, and from the deſcription given in ſyſtems of ſurgery, that the chin ſhould be evidently turned towards the oppoſite ſide; but I have repeatedly ſeen the diſeaſe, when I could diſcern no alteration in the poſition of the chin. The ſymptom which I have found to be the beſt guide in this caſe, is a ſmall hollow, which may be felt juſt behind the condyle that is diſlocated, which does not ſubſiſt on the ſound ſide." Pract. Obſerv. in Surgery, p. 325, edit. 2.

When the luxation is recent, the above ſymptoms enable us to aſcertain the nature of the accident with ſufficient eaſe; but when the diſlocation has exiſted ſeveral days or weeks, the caſe becomes leſs ſtrongly marked. The lower jaw has inſenſibly approached the upper one; and the patient gradually recovers the faculty of ſpeech and deglutition; but he ſtill ſtammers, and drivels.

Hippocrates pronounced luxations of the jaw to be fatal, unleſs reduced before the tenth day; but ſurgeons have now found, that this ſentiment is not well founded, and it is even ſuſpected, that Hippocrates might confound caſes of locked jaw with thoſe of diſlocations.

When the jaw has once been diſlocated, the accident is more prone to be produced again by ſlight cauſes. Mr. Hey mentions his having known two perſons in whom this diſlocation frequently happened. Not only yawning, but even opening the mouth incautiouſly in eating, would cauſe the accident. P. 326, edit. 2.

When a luxation of the jaw is to be reduced, the patient ſhould ſit on a low ſtool, with his head reſting on the breaſt of an aſſiſtant. In this poſition of the patient, the ſurgeon's hands are on a level with the mouth, which is advantageous, becauſe he is not obliged to elevate them, and conſequently can act with greater force on the jaw. The ſurgeon, after guarding his thumbs with linen, or a thick pair of gloves, is to introduce them into the mouth, and place them as far back as poſſible, on the great molares, at the ſame time bending under the chin the four fingers of each hand. The jaw, being thus graſped, is to be moved in the manner of a lever, the grinders being puſhed downwards and the chin upwards. No ſooner are the condyles thus extricated from under the zygomatic proceſſes, than the muſcles draw them up into their proper places again, with conſiderable force and ſuddenneſs. This takes place ſo rapidly, that the ſurgeon's thumbs would be in danger of injury, if he were to neglect to move them quickly outwards, and place them between the cheek and the jaws.

After the reduction, the four-tailed bandage for the lower jaw is to be applied, as in caſes in which this bone is broken. (See *Plate* V.) In the plate juſt referred to, however, it is proper to mention, that the centre of the bandage ſhould have been placed exactly on the chin, an eſſential circumſtance, as this is the point fartheſt from the centre of motion, and conſequently that where the bandage can operate with the moſt power in keeping the bone motionleſs. During the firſt days, the patient ſhould only be allowed liquid food, or ſuch as requires no maſtication.

When unuſual difficulty occurs in diſengaging the condyles from under the zygomatic proceſſes, owing to the reſiſtance of the muſcles, Le Cat's plan for overcoming and fatiguing theſe powers may be purſued; it conſiſted in introducing a ſmall ſtick between the teeth, and uſing it as a lever for combating the action of the muſcles, until they were quite exhauſted. Here the ſurgeon is not required to uſe violence, which might break the teeth, but only to keep up a moderate and unremitting extenſion of the reſiſting muſcles.

According to Mr. Hey, if both ſides of the lower jaw are depreſſed, while one ſide only is diſlocated, the reduction of the luxated condyle is rather prevented. The force ſhould be applied to the affected ſide alone. See Pract. Obſerv. in Surgery, p. 326, edit. 2.

Luxations of the Vertebræ.—The large ſurfaces by which theſe bones touch each other; the number and thickneſs of their ligaments; the ſtrength of the muſcles lying on the column formed by them; the ſmall motion of which each vertebra is capable; and, laſtly, the vertical direction of their articulating proceſſes (ſays Boyer), render a luxation of them in the dorſal and lumbar part of the column entirely impoſſible. A violence, though ever ſo conſiderable, cannot diſplace them, without firſt fracturing them. But this is not the caſe with the cervical vertebræ; the extent of their articulating ſurfaces is leſs; the ligamento-cartilaginous ſubſtance which unites their bodies has more pliability; the motion of their articulations is greater; and their articulating ſurfaces have an oblique direction, which allows them to have an obſcure rotatory motion. Hence luxations of the cervical vertebræ ſometimes preſent themſelves in practice. Boyer has ſeen a luxation of the middle cervical vertebræ cauſed by a violent rotatory motion of theſe bones.

Luxations of the Head from the firſt Vertebra.—The joints between the occipital bone and firſt vertebra of the neck, or atlas, are ſtrengthened with numerous ligaments, and only admit of very limited motion. We have no inſtance of luxation of the head from the firſt vertebra by an external cauſe, and ſuch a diſlocation, were it ever to happen, would inſtantly deſtroy the patient, by compreſſing and injuring the ſpinal marrow. But, as Boyer has remarked, nature, which cannot bear ſo ſudden a change, is habituated to it, when it takes place gradually, and the ſpinal marrow which would be fatally hurt by a ſudden diſlocation of the head from the atlas, is capable of bearing the ſame kind of luxation that is inſenſibly and ſlowly produced by diſeaſe.

Luxations of the firſt cervical Vertebra from the Second.—The motion of the head to the right and left is principally executed by the firſt vertebra turning on the ſecond. The laxity and weakneſs of the ligaments between theſe bones, and the direction of their articular proceſſes, tend to facilitate this kind of rotation, which motion, indeed, would frequently be carried beyond due bounds, and a diſlocation happen every time that we turn our heads, were not the motion confined by the very thick ligaments which go from the ſides and ſummit of the proceſſus dentatus of the ſecond vertebra to the edges of the great occipital hole. As Boyer obſerves, when this motion is forced beyond its proper limits, the ligaments are torn, and the lateral parts of the body of the firſt vertebra glide along on the articulating horizontal proceſſes of the ſecond. If the head is turned from the left to the right, the left ſide of the body of the vertebra is carried before its correſponding articulating ſurface, whilſt the right ſide falls behind its correſponding ſurface. In this luxation, ſometimes the proceſſus dentatus, the ligaments of which are broken, leaves the ring, formed for it by the tranſverſe ligament and the anterior arch of the firſt vertebra, and preſſes on the ſpinal marrow. In other examples, it does not quit the ring; but the diameter of the vertebral canal is always diminiſhed at the place of the diſlocation, and the ſpinal marrow injured or lacerated. It is readily conceivable, that the patient cannot ſurvive an accident of this nature, every wound of the ſpinal marrow, in ſo high a ſituation, being quickly fatal.

The celebrated M. Louis found, that the criminals who were in his time hanged at Lyons, periſhed by the luxation of the firſt vertebra from the ſecond; whilſt thoſe hanged at Paris were ſuffocated by ſtrangulation. He diſcovered that the cauſe of this difference was owing to a rotatory motion which was given to the body of the culprit by the executioner at Lyons, the moment it was ſuſpended. J. L. Petit mentions an inſtance in which a boy, between ſix and ſeven years of age, was killed in an inſtant by a luxation of the firſt from the ſecond vertebra, brought on by the boy ſtruggling, whilſt a perſon was raſhly lifting him up by the head. This laſt trick cannot be too ſeverely condemned as a moſt dangerous experiment.

There are other luxations of the neck not followed by death; but in theſe caſes, the diſlocation takes place in the third, fourth, fifth, or ſixth vertebra, and only one articulating proceſs is luxated. Some examples are quoted by Boyer, which were conſidered as caſes of this laſt deſcription, being attended with a diſtortion of the head to the right or left, without any ſpaſm or rigidity of the ſterno-cleido-maſtoideus muſcle.

When luxations of the cervical vertebræ produce no ſymptoms indicating a dangerous degree of preſſure on the ſpinal marrow, it is prudent not to attempt the reduction, as the patient may be killed in a moment by the endeavour, in conſequence of the ſpinal marrow becoming ſuddenly compreſſed and injured. If the ſymptoms, however, make it probable that the patient's only chance of life depends on altering the poſition of the luxated bones, the ſurgeon ought cautiouſly to attempt the reduction. Fortunately, theſe caſes are as unfrequent as they are perplexing, and we ſhall omit, as unintereſting to the practical ſurgeon, the uſual directions reſpecting the mode of reducing ſuch accidents. It is enough for the ſurgeon to be duly aware of the peril that accompanies the attempt.

Luxations of the Bones of the Pelvis.—Theſe bones are ſcarcely ſuſceptible of luxations. The os ſacrum, firmly fixed between the two oſſa innominata, cannot poſſibly be diſlocated. The os coccygis is more eaſily fractured than luxated. The latter accident, however, has ſometimes been obſerved. Boyer has ſeen it induced by ſloughing and diſeaſe, which denuded the bone, and evinced that there was a ſpace of nearly two inches between the extremity of the ſacrum and the baſe of the os coccygis. But, in the end, the two bones grew together again. Much has been written by authors concerning a relaxation and yielding of the ſymphyſis pubis and ſacro-iliac articulations in the advanced ſtages of pregnancy. We leave to the accoucheur the determination of this matter, as it is only indirectly connected with the ſubject of luxations.

When we ſtated that the bones of the pelvis were hardly ſuſceptible of luxations, our meaning was of courſe confined to the effect of ordinary cauſes. Great external violence, acting directly on any part, will make every thing yield. Thus, in the fourth volume of the Memoirs of the French Academy of Surgery, an inſtance is recorded, where the right os ilium was diſlocated from the ſacrum, three inches backwards, by a ſack of wheat, weighing three hundred and fifty pounds, falling on the back of a labourer. The patient died on the twentieth day, and the luxation was proved by diſſection. The pelvic viſcera were found in a ſtate of inflammation, with matter in the lower region of the abdomen.

Were a ſimilar accident to preſent itſelf to the practitioner, he ought to have recourſe to antiphlogiſtic means; for the danger chiefly depends on the pelvic viſcera becoming inflamed. Copious and repeated bleedings, the warm-bath, fomentations, and low diet, would be particularly indicated.

Luxations of the Ribs.—The ancient writers on ſurgery have furniſhed us with no obſervations concerning diſlocations of the ribs, and obſervers, who have publiſhed numerous facts relative to other caſes, make no mention of theſe accidents. Even J. L. Petit and Duverney, authors of more recent date, are ſilent on the ſubject; and as Paré, long before them, had diſtinctly treated of luxations of the ribs, we muſt aſcribe their ſilence to their diſbelief in the poſſibility of ſuch caſes.

Whether the ribs are ſuſceptible of diſlocation or not, is yet an unſettled queſtion.

Ambroſe Paré, Barbette, Junker, Platner, and Heiſter, deſcribe the accident as poſſible. Platner has obſerved: "Coſtæ longè frequentius franguntur, quàm à ſuâ ſede moventur. Non poſſunt in exteriorem partem excidere, cum oppoſiti proceſſus tranſverſi vertebrarum ſummam illarum partem contineant, nec facile ſurſum vel deorſum verſus promoveri poſſunt. Igitur ſi moventur in interiorem partem propelluntur.." Inſtit. Chir. § 1149. Platner actually enters into a detail of the ſymptoms to be apprehended in ſuch caſe: "cùm pleura prematur, gravis inflammatio et ſpirandi difficultas ſequitur." In a memoir inſerted amongſt thoſe of the Royal Academy of Surgery in France, M. Buttet is yet more poſitive than Platner, in only admitting the luxation forwards; but he does not conceive that the accident can happen to all the ribs with equal facility. The upper ones are protected by the ſcapula, and the lower, which are unfixed and very moveable, can only be luxated with great difficulty. He thinks that diſlocations can hardly occur to any of theſe bones, except the four or five lower true ribs, and two or three of the upper falſe ones, which laſt are more ſuſceptible of diſplacement, in conſequence of not being ſupported by the ſternum. On the other hand, Boyer, a late writer on diſlocations, is very poſitive that the ribs are exempt from theſe accidents. He tells us, that he ſhould have obſerved the ſame ſilence on the ſubject as J. L. Petit, did not a caſe, publiſhed in the Memoirs of the Academy of Surgery, after the death of that celebrated practitioner, ſeem to eſtabliſh the poſſibility of ſuch caſes. But Boyer contends, that, in reading this example, it is obvious the ſurgeon has miſtaken a fracture of the poſterior end of the ribs for a diſlocation. If, ſays Boyer, we attend to the number and force of the ligaments, which attach the ribs to the vertebræ and ſternum, and alſo to the manner in which the intercoſtal muſcles confine them, we ſhall not eaſily conceive how external violence, whether it acts on their middle or extremities, can luxate them. They are ſo firmly attached to the ſurrounding parts, that it is very difficult to ſeparate them from the body in the dead ſubject; and, in preparing ſkeletons, we often break thoſe bones, if we are not careful to cut all their bonds of union, before we attempt to detach them from the parts with which they are articulated. All the ſymptoms accompanying M. Buttet's caſe indicate a fracture of the neck, or poſterior extremity of the rib, as the pain, crepitation, and motion of the bone. No concluſion could be drawn from the motion, in proof of a luxation, ſince the fracture (if it were ſuch) was ſituated very near the back end of the rib, and, of courſe, the whole length of the bone would ſeem to move at once.

Boyer excludes from conſideration caſes, called by Lieutaud and others diſlocations of the ribs, which, in fact, are only ſeparations of the ribs and dorſal vertebræ from each other, in conſequence of the deſtruction of their ligaments, &c. by diſeaſe.

Luxations of the Clavicle, or Collar-Bone.—Luxations of the clavicle are much leſs frequent than fractures; and it was eſtimated by Default that the latter accidents are to the former as ſix to one. As far as our own experience enables us to judge, diſlocations are even more uncommon than this calculation repreſents.

The clavicle, however, may be luxated either from the ſternum, or the acromion.

Luxations of the ſternal End.—The ſternal end of the clavicle may be diſlocated forwards, backwards, or upwards, but never downwards, in which laſt direction a luxation is prevented by the cartilage of the firſt rib. The diſlocation forwards is by far the moſt frequent, and may be cauſed by exceſſive motion of the ſcapulary end of the clavicle backwards. Luxations upwards and backwards are very rare. The former can only be occaſioned by the ſhoulder being puſhed violently forwards and downwards, which ſometimes happens in falls. The diſlocation backwards is the moſt unuſual caſe of all.

If the ſhoulder is puſhed violently backwards, the ſternal end of the clavicle is propelled forwards, tearing the capſule of the articulation, the anterior ligament, and the tendon of the ſterno-cleido-maſtoideus muſcle. Quitting the ſurface with which it is articulated, it ſlips in front of the upper part of the ſternum, and produces under the ſkin in this ſituation, a hard prominence, which follows the motion of the ſhoulder.

When the ſhoulder is ſuddenly depreſſed, the ſternal end of the clavicle is eaſily luxated upwards, as there is nothing to limit its motion in this direction, except the inter-clavicular ligament, which, being relaxed by the greater contiguity of the two bones, is not capable of making effectual reſiſtance.

In the luxation backwards, the extremity of the clavicle is carried behind the ſuperior part of the ſternum.

The ſuperficial ſituation of the clavicle renders eaſy the diagnoſis of all luxations of its ſternal end. When the diſlocation happens forwards, a hard projection is felt, or even ſeen on the anterior and ſuperior part of the ſternum. Such projection may be made to diſappear by carrying the ſhoulder forwards and outwards. In the place which the head of the clavicle ought to occupy, an empty ſpace is perceptible.

In the luxation upwards, the diſtance between the ſternal ends of the two clavicles is leſſened.

If the luxation is backwards, the head of the bone forms a tumour at the interior and inferior part of the neck, and a depreſſion may be felt in the place which it ought to occupy. The head of the bone thus diſplaced, may, as Monſieur J. L. Petit has obſerved, compreſs the trachea, œſophagus, jugular vein, carotid artery, par vagum, &c. ſo as to cauſe dangerous ſymptoms. It is alſo to be noticed, that, in diſlocations of the ſternal and of the clavicle backwards, the head is inclined towards the affected ſhoulder.

Luxations of the ſternal extremity of the clavicle may be reduced by making a lever of the arm, by means of which the ſhoulder is firſt to be brought outwards, and then puſhed forwards, ſuppoſing the diſlocation to have happened in that direction. But if the luxation is backwards, the ſhoulder, after being drawn outwards, muſt be carried backwards; or upwards, when the diſlocation is in the ſame direction. By obſerving theſe rules, the head of the bone may be replaced, with the aid of a little preſſure of the thumb. But though the reduction may be eaſy, it is difficult to maintain it, all the ligaments being torn, and the articular ſurfaces diſpoſed to ſlide away from each other, on the ſlighteſt motion of the ſhoulder.

The apparatus uſed by Deſault for fractures of the clavicle is to be employed in luxations of the ſternal end of the bone. (See *Fractures of the Clavicle*, and *Surgical Plate* IV.) The ſhoulder continues to be kept outwards by means of the cuſhion placed in the axilla; but notwithſtanding the utmoſt attention on the part of the ſurgeon, the head of the clavicle cannot be prevented from being ſomewhat more prominent than that of the oppoſite ſide. Braſdon propoſed a tourniquet for making preſſure on the luxated extremity of the bone, with a view of hindering ſuch deformity, though, according to Boyer, it will not anſwer the purpoſe.

Luxations of the Scapulary End of the Clavicle.—Theſe caſes are much leſs frequent than the former, owing to the very great ſtrength of the ligaments binding the clavicle to the ſcapula. The ſcapulary end of the clavicle is ſeldom luxated in any direction except upwards. Boyer admits the poſſibility of the accident taking place downwards, and we think we have ſeen an inſtance, in which it was cauſed by a heavy brick falling on the ſhoulder from a conſiderable height. There was no crepitus, and the end of the bone, which was moveable, was obviouſly depreſſed below the acromion.

The diſlocation upwards is that, which principally demands the attention of the practitioner. It may be cauſed by falls, in which the violence operates on the extremity of the ſhoulder. The ſcapulary end of the bone ſlips upwards over the acromion, which laſt proceſs is itſelf a little drawn under the luxated part of the clavicle, when the ſhoulder is pulled inwards by ſuch muſcles, as have the effect of bringing the arm towards the trunk. The writer of this article was lately conſulted in a very manifeſt caſe of diſlocation of the ſcapulary end of the clavicle. The patient was a young gentleman out of Yorkſhire, where the accident had happened, and, not being underſtood, was left unreduced. When the caſe was brought to us, it was too late for any aſſiſtance to be rendered. Fortunately, the inconveniences ſuffered were not very great. The patient generally inclined his head towards the affected ſhoulder, and experienced a degree of weakneſs in raiſing his arm to his head; but even theſe infirmities were gradually becoming leſs.

Boyer conceives, that a violent action of the trapezius muſcle, which we know is attached to the outer half of the clavicle, may have a ſhare in producing this kind of diſlocation, eſpecially if the muſcle ſhould forcibly contract juſt at the moment when the acromion is fixed on the ground or body, againſt which it falls.

The diagnoſis of the accident cannot be very difficult, ſince the end of the clavicle may always be diſtinctly felt, forming a projection under the ſkin that covers the acromion. The head is inclined to the affected ſide, and the patient avoids moving the arm, in conſequence of ſuch action occaſioning pain.

The diſlocation is to be reduced by drawing the arm and ſhoulder outwards, and puſhing the diſplaced end of the clavicle downwards. Deſault's apparatus for broken collar bones is then to be applied. (See *Fracture of the Clavicle*, and *Plate* IV.) The cuſhion in the arm-pit, when the elbow is confined near the ſide with the roller, here acts very uſefully in keeping the ſhoulder outwards. The turns of the bandage, which go from the elbow to the ſhoulder, ſhould alſo be made to act eſpecially on the outer end of the clavicle, ſo as to preſs it downwards.

Luxations of the Shoulder; or of the Humerus, or Os Brachii, from the Scapula.—The ſhoulder joint allows the arm to be moved in every poſſible direction, and as the ſtructure, eſſential to ſo great a latitude of motion, hinders the articulation from being endued with the ſtrength and ſtability of other leſs moveable joints, it becomes, of courſe, a very pre-diſpoſing cauſe of diſlocations. In fact, no joint is ſo frequently luxated as the ſhoulder. And it appears from a comparative regiſter, kept at the Hôtel-Dieu at Paris, that, during ſeveral years diſlocations of this articulation equalled in number the luxations of all the other joints together. Œuvres de Deſault par Bichat, tom. i. p. 341.

Every thing, ſays the author of the preceding work, appears to facilitate the eſcape of the bone from its natural cavity. 1. In the articular ſurfaces, a ſhallow oval cavity, which receives a ſemi-ſpherical head twice as extenſive as itſelf in the perpendicular direction and thrice as broad from before backwards. 2. The only ligament, ſtrengthening this joint, is a mere capſule, which is thin below, the very direction in which there is nothing to oppoſe a luxation, and thicker above, where the acromion and coracoid proceſſes, together with the triangular ligament, form an almoſt inſurmountable obſtacle to ſuch an accident. 3. With reſpect to the muſcles and motions of the ſhoulder, we have to notice numerous and ſtrong faſciculi around the joint, communicating to it movements eaſily performed in every direction; propelling the head of the humerus againſt different points of the capſule; and rupturing the latter part, when their power is ſuperior to its reſiſtance. 4. As for external force, what bone is more expoſed to its effects, particularly in the labouring claſſes of ſociety?

Affected by ſo many different pre-diſpoſing cauſes, the humerus would be inceſſantly ſubjected to diſlocations, did not the ſcapula, which is equally moveable, follow all its motions, and afford it a point of ſupport differently diſpoſed, according to the different poſition of its upper end. In ſhort, much of the ſtrength of the joint depends upon the double moveableneſs of the two articular ſurfaces.

Of the different Kinds of Luxations of the Shoulder.—Though this joint is generally much diſpoſed to luxations, it is not equally ſo at every point. There are ſome points at which the accident cannot happen at all; while there are others at which, though it ſeems poſſible, it has never been obſerved. Hence, before examining the mechaniſm of diſlocations of the ſhoulder, Deſault endeavours to determine with preciſion the directions in which the accident is poſſible. He adverts to the confuſion exiſting among writers on this ſubject; ſome of whom employ different terms to expreſs the ſame thing; while others have affixed ſimilar names to things which are eſſentially different and diſtinct from each other. With regard to ſome kinds of luxations they all coincide; concerning others, they diſagree! Deſault firſt divides luxations of the humerus into two kinds; *viz. primitive*, which are the ſudden effect of external violence, and *conſecutive*, which ſucceed the former from cauſes hereafter to be explained.

The ſame eminent ſurgeon then directs us to ſuppoſe the oval ſurface of the glenoid cavity to have four ſtraight lines drawn at its ſides, in the form of a parallelogram; one repreſenting the upper edge of that cavity; another, the inferior; a third, the internal; and a fourth, the external.

It is manifeſt, that the head of the humerus cannot be diſplaced towards the upper edge of the glenoid cavity. In that direction the acromion and coracoid proceſſes, the triangular ligament ſtretched between them, the tendons of the biceps and ſupra-ſpinatus, and the fleſhy part of the deltoid muſcle, form an effectual reſiſtance to any force propelling upwards the head of the bone. Suppoſing a luxation in this direction were to happen, the head of the bone muſt alſo be puſhed outwards, a thing which is impoſſible, becauſe the trunk hinders the elbow from being inclined far enough inwards for that purpoſe.

On the other hand, the three remaining edges preſent but little reſiſtance. At the lower one, the long portion of the triceps; at the internal one, the tendon of the ſubſcapularis; and at the external, the tendons of the infra-ſpinatus and teres minor; eaſily yield to a force directed againſt them, and admit of primitive luxations taking place, either downwards, inwards, or outwards; downwards, between the tendon of the ſub-ſcapularis and that of the long head of the triceps; inwards, between the ſub-ſcapulary muſcle and foſſa; and outwards, between the infra-ſpinatus muſcle and ſubjacent part of the ſcapula. All theſe modes of diſplacement do not occur with equal frequency, as will be preſently conſidered.

After the head of the humerus has quitted the glenoid cavity, and ſlipped in one of theſe three directions, it often changes its ſituation again; and, in this event, a conſecutive luxation may follow a primitive one, either downwards, or inwards; but never that outwards, were ſuch a caſe to occur, becauſe the ſpine of the ſcapula would prevent it.

According to Deſault, a conſecutive luxation inwards may ſucceed a primitive one downwards, as there is nothing to hinder the head of the bone from paſſing between the ſubſcapulary muſcle and foſſa. On the contrary, ſhould it tend outwards, the tendon of the triceps reſiſts, and, notwithſtanding the ſtatement of Petit, a conſecutive luxation in this laſt direction never happens.

Sometimes, when the head of the humerus has eſcaped at the internal or inferior part of the capſule, it is carried behind the clavicle, ſo as to form a conſecutive luxation upwards, a caſe which was noticed by Paré, perhaps by Galen, and a ſpecimen of which was preſerved in Deſault's muſeum. Here the ſeccondary diſplacement only takes place ſlowly, and after it has happened, art can ſeldom correct it, on account of the firm adheſions contracted by the ſurfaces of the bone. Thus, in the example referred to, a new cavity was formed behind the clavicle, and the humerus was connected with the ſurrounding part by a kind of new ligaments.

From this ſtatement, derived from Deſault, it follows that the humerus is ſubject to four ſorts of diſplacement: 1, downwards; 2, outwards. In theſe directions the diſlocation is always primitive. 3. Inwards, which may be either primitive or conſecutive. 4. Upwards, in which direction the accident can only happen conſecutively. As Deſault obſerves, the ſecond and the fourth caſes are exceedingly rare, compared with the reſt.

Primitive Luxations.—Theſe are cauſed by falls or blows on the arm, and the kind of diſlocation appears to be determined by the poſition in which the limb happens to be at the moment of the accident.

If the arm is more or leſs raiſed from the trunk, without being inclined either forwards or backwards, and the patient falls laterally, the weight of the body, being almoſt entirely ſupported by the humerus, forces downwards its upper end, which lacerates the capſular ligaments, and is diſlocated downwards. The occurrence is alſo in part facilitated by the united action of the latiſſimus dorſi, pectoralis major, and teres major muſcles. Theſe are in a ſtate of involuntary action, and tend to draw downwards the head of the humerus, while the elbow remains fixed on the ground or ſurface againſt which it has fallen. Some authors believe, that a violent contraction of the deltoid muſcle may alſo have a ſhare in luxating the ſhoulder downwards, as it may tend to force the head of the humerus through the capſular ligament towards the axilla. Deſault thinks the truth of this ſtatement is confirmed by many obſervations, and quotes the caſe of a notary whoſe ſhoulder was diſlocated downwards, in lifting up a heavy regiſter book.

The manner in which a primitive luxation inwards is produced, is little different from that of the foregoing caſe. The elbow, at the moment of the fall or blow, is both ſeparated from the trunk and carried backwards. The weight of the body acts upon the humerus, the anterior portion of the capſular ligament gives way, and the head of the bone is diſlocated forwards.

The luxation outwards can only be occaſioned when the elbow is inclined forwards, towards the oppoſite ſhoulder. If the force is ſufficiently great, the outer part of the capſular ligament is lacerated, and the head of the humerus diſplaced. But, ſays Deſault, what can ſuch power be? In a fall, when the arm is forced againſt the ſide, it cannot be moved far enough to cauſe a laceration of the capſule. Hence this eminent ſurgeon concluded, that luxations of the head of the humerus outwards muſt be very uncommon caſes. None are recorded by ſurgical writers, and Deſault himſelf had never obſerved ſuch an accident. Beſides, it is worthy of attention, that when in falls, the arm ſeparated from the ſide is inclined either forwards or backwards, the weight of the body only operates upon it obliquely, and it is little acted upon by the latiſſimus dorſi, pectoralis major, and teres major muſcles. Hence no diſlocations of the ſhoulder are ſo frequent as thoſe downwards, in the production of which caſes the influence of the weight of the body, and of the action of the muſcles is direct. However, the luxation inwards is not uncommon, and many of Deſault's caſes prove the poſſibility of a primitive diſlocation of this kind, notwithſtanding ſeveral modern authors have doubted it, by believing with Hippocrates, that originally all luxations of the ſhoulder happen downwards.

It ſometimes happens, that the lacerated opening in the capſular ligament ſuffices for the paſſage of the head of the bone from the glenoid cavity, but immediately afterwards contracting, is not large enough to admit of its return. This practical fact was firſt noticed by Deſault, who has publiſhed two examples of it in his journal. Such caſes have ſince been very frequent at the Hôtel Dieu, at Paris.

Conſecutive Luxations.—When a conſecutive luxation ſucceeds a primitive one, many cauſes may concur in producing this change. If a ſecond fall ſhould happen, the elbow being ſeparated from the ſide, the head of the bone may eaſily be forced out of the place into which it was firſt thrown. A caſe illuſtrating this obſervation is related in Les Œuvres Chir. de Deſault par Bichat, tom. i. p. 350.

The action of the muſcles is a permanent cauſe of a freſh diſplacement. When the humerus is diſlocated downwards, the pectoralis major, and the inner portion of the deltoid, pull its upper portion inwards and upwards.

Various movements communicated to the arm may alſo produce a change in the poſition of the luxated head of the bone, according to their direction. Thus a luxation inwards has frequently ſucceeded one downwards, in conſequence of awkward efforts to reduce the bone.

Symptoms of Luxations of the Shoulder.—In general, the diagnoſis of luxations of the ſhoulder is not attended with much difficulty. As Hippocrates has obſerved, whatever may be the mode and ſituation of the diſplacement, a manifeſt depreſſion may always be perceived under the acromion, which proceſs ſeems to project more than in the natural ſtate. Moving the humerus is very painful, and indeed moſt of its motions are either impeded, or very much limited. The arm cannot be moved without the ſhoulder being alſo moved, becauſe, the functions of the joint being prevented, both theſe parts form as it were only one.

To ſuch ſymptoms, common to all diſlocations of the ſhoulder, are to be added thoſe which belong to particular caſes. If the luxation is downwards, the arm is ſomewhat longer than in the natural ſtate; it may be moved a little way outwards; but every attempt to carry it forwards or backwards inevitably occaſions acute pain. The elbow is more or leſs raiſed from the axis of the body by the action of the deltoid, the long portion of the biceps, and the ſupraſpinatus muſcles, which, being on the ſtretch, contract and incline the bone outwards. In order to avoid the pain ariſing from this poſition, the patient leans towards the affected ſide, keeps his fore-arm half-bent, and reſts his elbow on his hip, ſo that the arm may have a fixed point to hinder all painful motions of the limb. By this attitude alone, Deſault was accuſtomed to recognize a luxation downwards, and he was ſeldom deceived. Beſides theſe circumſtances, we have to mention, that the diſlocated head of the bone always produces a hard and more or leſs evident prominence in the hollow of the axilla.

In addition to the ſymptoms common to all luxations of the ſhoulder, the diſlocation inwards preſents the following: the elbow is ſeparated from the ſide, and carried a little backwards; the humerus appears to be directed towards the middle of the clavicle; moving the limb backwards is not very painful, but carrying it forwards is exquiſitely ſo; a manifeſt prominence may be noticed under the pectoral muſcle; the arm is ſcarcely longer than in the natural ſtate; and the patient's attitude reſembles that of the foregoing caſe.

Were a diſlocation outwards ever to happen, it would be particularly characterized by a hard tumour under the ſpine of the ſcapula, by the inclination of the elbow forwards, and its ſeparation from the ſide; and, laſtly, by the length of the limb appearing a little increaſed.

A luxation upwards would be announced by a projection behind the clavicle, an obvious ſhortening of the arm, and its unnatural direction.

It is frequently much more eaſy to aſcertain the exiſtence, than the ſpecies, of luxation of the ſhoulder. Indeed, ſometimes it is a moſt difficult matter to determine, whether a diſlocation inwards is primitive or conſecutive, as the apparent phenomena of each caſe are alike. The judicious and experienced Deſault taught, that this intereſting point is only capable of being elucidated by attention to the hiſtory of the caſe, and the order in which the ſymptoms preſented themſelves. This excellent ſurgeon repreſents the diſtinction as of much practical importance, ſince the proper mode of reducing the two caſes is different, the head of the bone having to deſcribe a very ſhort track in the primitive luxation, and a more circuitous one in that which is conſecutive.

Diſlocations of the ſhoulder do not commonly give riſe to any accidental bad or troubleſome ſymptoms. Sometimes, immediately after the occurrence, the joint is affected with a great deal of ſwelling; but this complaint generally ſubſides very quickly, under the uſe of the aqua vegeto-mineralis.

In certain inſtances, the preſſure of the head of the bone on the axillary glands and veins produces an œdema of the whole limb. Deſault ſeldom obſerved this happen, except where the reduction had been delayed. The treatment he recommends is to apply a roller to the limb, after reducing the head of the bone.

Another accident, which was ſeveral times obſerved by this diſtinguiſhed ſurgeon, is a paralyſis of the limb, occaſioned, in the luxation inwards, by the preſſure of the head of the bone on the axillary plexus of nerves. In ſome inſtances, this affection proved incurable; in others, it yielded to the employment of ſtrong ammoniacal liniments. A few obſtinate caſes were cured by making an iſſue juſt over the clavicle by means of the moxa; but this laſt method was as frequently unavailing as ſucceſsful.

Reduction of Luxations of the Shoulder.—The infinite variety of modes propoſed for reducing diſlocations of the ſhoulder may be referred to two general claſſes. Some conſiſt in replacing, by a mechanical force, the head of the humerus in the cavity from which it has eſcaped, whether previous extenſion be made or not. Others are reſtricted to diſengaging the head of the humerus from the ſituation which it accidentally occupies, and the reduction is left to be accompliſhed entirely by the action of the muſcles.

The hiſtory of all the methods intended to operate on the firſt principle would be tedious and unprofitable. Suffice it to ſtate, that almoſt all of them act in the following manner. Something being placed under the axilla, ſerves as a fulcrum, on which the arm is moved in the way of a lever, the reſiſtance being the luxated head of the humerus, and the power being applied either to the lower part of this bone or to the wriſt. It was in this manner that the ambi of Hippocrates acted, that machine ſo renowned even in modern times, and of which numerous modifications have been deviſed by Paulus Ægineta, Ambroſe Paré, Duverney, Freke, &c. By ſuch an apparatus, the head of the humerus was at once directed towards the glenoid cavity of the ſcapula, and diſengaged from its unnatural ſituation.

Extenſion of the arm uſually produces this ſecond effect, and has been accompliſhed in a variety of ways. Sometimes the weight of the body on one ſide, with the dragging of the diſlocated limb on the other, ſerved to make the extenſion. It was on this principle that the ladder, the door, and the ſtick operated, as deſcribed by Hippocrates in his treatiſe on fractures, and repeated by all ſubſequent writers. On other occaſions, the trunk has been immoveably fixed, while the arm was forcibly extended. This was the mode purſued in employing the machines deſcribed by Oribaſius.

Sometimes no perceptible extenſion at all was made, and the head of the humerus, being propelled outwards by ſomething put under the axilla, was puſhed by the ſurgeon at once into the glenoid cavity.

With Deſault, we ſhall abſtain from entering into a particular explanation of the objections to the preceding methods. Petit and B. Bell have already detailed their diſadvantages. Whoever conſiders that the head of the bone has eſcaped through the ruptured and lacerated capſular ligament, and that it is impoſſible to know preciſely the exact ſituation of the opening, muſt perceive how abſurd it is to attempt to direct the head of the bone to it by any artificial force.

However well covered with ſoft materials the body may be, which is put under the axilla for the purpoſe of ſerving as a fulcrum, an unpleaſant chaffing, or even dangerous degrees of ſtretching and laceration, may ariſe from its application, when the trunk is ſuſpended over it, as in the employment of the door, ſtick, &c. By ſuch practice, Petit ſaw the neck of the humerus fractured, and the axillary artery ruptured, ſo that an aneuriſm was the conſequence.

A wiſe objection, alſo made by Deſault to the uſe of any apparatus of the foregoing kinds, is, that few ſurgeons are provided with the inſtrument, and therefore much uſeful time would be loſt in procuring it, when the caſe is actually waiting for relief. Beſides, ſays he, when the luxation is conſecutive, how can any mechanical contrivances have the effect of drawing back the head of the bone through the track by which the diſplacement has taken place? For inſtance, if a luxation inwards has ſucceeded one downwards, the head of the bone ought to be drawn downwards before being replaced in its natural cavity. How can the direction of the extenſion be varied accordingly? It is likewiſe to be obſerved, that every apparatus alluded to reſiſts the action of the muſcles, which, in fact, ought to be the principal agent in the reduction. Were a luxation ever to happen upwards, no apparatus could anſwer, as muſt be moſt evident.

No doubt, however, when the head of the humerus is luxated downwards, and is not ſituated far from the glenoid cavity, the machines to which we have alluded will often ſerve to effect the reduction with tolerable facility. But in ſuch caſes, there is no real occaſion for artificial contrivances, as natural means will be found quite ſufficient. In ſhort, the reduction may be executed with the hands, and with this advantage, that the direction of the movements may be regulated and varied with more preciſion.

The following method was frequently purſued by Deſault with ſucceſs: the patient ſat on a chair of middling height: Deſault placed the hand of the luxated limb between his knees, which he moved backwards, ſo as to make extenſion, and diſengage the head of the bone, while an aſſiſtant held back the trunk, and made the requiſite counter-extenſion. Deſault now took hold of the upper part of the humerus with both his hands, and puſhed its head upwards and a little outwards into the glenoid cavity.

This mode is mentioned by Petit, though complicated with the employment of a napkin, which was put under the axilla, and over the ſurgeon's neck, who forced upwards the head of the bone by drawing back his head.

In recent luxations of the ſhoulder downwards, Deſault ſometimes often found even a more ſimple plan anſwer: he put his left hand in the axilla to ſerve as a fulcrum, while, with the right, which was applied to the lower and external part of the arm, he moved the humerus towards the trunk, at the ſame time puſhing the bone upwards. By this double movement, directed upwards and outwards, the head of the humerus is put into its natural ſituation. See Œuvres Chirurgicales de Deſault, par Bichat, tom. i. p. 363, 364.

Mr. Hey notices, that if the head of the os humeri remains in the axilla, and not far removed from the glenoid cavity, the reduction may ſometimes be executed with a very ſmall degree of extenſion. Thus, in the relation of one caſe, he obſerves: "after I had put every thing in proper order for the reduction, I deſired the aſſiſtants, who were to make the extenſion, to keep the arm elevated at a right angle with the body, till I ſhould direct them to begin the extenſion. In doing this, they kept the arm a little upon the ſtretch, waiting for my orders. While the arm was in this ſtate, I placed my fingers below the head of the bone, that I might be ready to co-operate with them; and preſſing my fingers upwards into the axilla, that I might feel the head of the bone diſtinctly, the reduction was unexpectedly made by this gentle effort." Pract. Obſerv. in Surgery, p. 295—226, edit. 2.

The ſame experienced ſurgeon once ſaw a luxated ſhoulder reduced by the mere efforts of the patient, who, while preparation for the reduction was making, walked about in pain, and after placing his hand on the back of a chair, and moving his body in different directions, cried out, as if hurt more than uſual. He then ſat down, and ſaid that he was eaſy, and could move his arm better. In ſhort, the bone was actually reduced. P. 297. op. cit.

Reduction of Luxations of the Shoulder by Means of Extenſion, as practiſed by Deſault.—There muſt be an adequate number of aſſiſtants, in order to increaſe, according to neceſſity, the force which is to overcome the reſiſtance experienced; but, in general, two are quite ſufficient. A thick pad ſhould be procured, for the purpoſe of guarding the margins of the axilla from injury; and the aſſiſtants ſhould be furniſhed with a ſheet, doubled into folds, about four inches in breadth, and alſo with a towel folded in the ſame manner.

The patient is to ſit on a lowiſh chair, or he may be laid on a ſtrong immoveable table. Deſault long followed the firſt of theſe modes, according to ordinary cuſtom, though, as Bichat remarks, it is not in every reſpect the moſt advantageous. In the ſitting poſture, indeed, the arm may be very well extended tranſverſely; but if, as often happens, it is neceſſary to direct the extenſion upwards or outwards, the aſſiſtant, being then obliged to raiſe or lower himſelf, does not poſſeſs equal power in the new poſture, and finds himſelf embarraſſed, and incapable of varying the direction of the extenſion, according as the ſurgeon may think beſt.

As for the patient, he finds ſuch poſture, in which the trunk is only partly ſupported, much more irkſome than that in which the cheſt lies equally upon an horizontal ſurface. Motives of this kind induced Deſault, in the latter years of his practice, to renounce the ſitting poſition.

The patient's poſture being arranged, the linen pad is to be put under the axilla of the affected ſide, and the middle of the folded ſheet is to be placed on ſuch compreſs, while the two ends are to be carried obliquely before and behind the cheſt to the oppoſite ſhoulder, where, being held by an aſſiſtant, they ſerve to fix the trunk, and to make the counter-extenſion. The pad hinders the ſheet from preſſing on the margins of the pectoralis major and latiſſimus dorſi. Were it not ſo, theſe muſcles, being pulled upwards, would draw the humerus in the ſame direction, and defeat the extenſion, which is performed as follows.

Deſault made two aſſiſtants take hold of the fore-arm above the wriſt, or elſe he cauſed the folded towel to be applied to this part, and confided to the care of one or two aſſiſtants, who were to begin the extenſion in the ſame direction in which the diſlocated bone lies. This firſt movement, intended to diſengage the head of the humerus from the place in which it happened to be lodged, was followed by another, which varied according to the kind of luxation. When the diſlocation was downwards, Deſault gradually brought the arm near the ſide, at the ſame inſtant that he puſhed it gently upwards. By this artifice, the head of the bone was inclined towards the glenoid cavity, into which it generally entered without difficulty.

When the luxation was inwards, the humerus was brought upwards and forwards, after the firſt extenſion in the direction of the bone: thus its head was directed backwards. Were a luxation to occur outwards, it would be neceſſary to move the humerus, during the extenſion, exactly in a direction oppoſite to that recommended in the foregoing inſtance.

As ſoon as the head of the humerus has been diſengaged by the firſt extenſion, the movement communicated to the bone by the ſubſequent extenſion ought in general to be preciſely in the contrary direction to that in which the head of the bone has eſcaped.

When any difficulty ſeems to oppoſe the reduction, the bone ſhould be moved in different directions, after the requiſite extenſion has been made, with due attention to the principle juſt laid down. This method will frequently anſwer when ſimple extenſion will not, the head of the bone being conducted by the movements towards the glenoid cavity.

When the luxation was conſecutive, Deſault, by means of the firſt extenſion in the direction of the diſlocated bone, brought its head into the ſituation where it was originally lodged, and he then acted juſt as if the caſe were altogether a primitive one. Very often, whether the accident is of one kind or the other, can only be diſtinguiſhed at the time of the reduction. In fact, when the extenſion is well managed, the reduction moſtly happens ſpontaneouſly, and if the head of the bone is luxated inwards conſecutively, it may be obſerved deſcending along the inſide of the ſcapula, and then paſſing over the inferior part, and aſcending towards the laceration in the capſule.

It has been ſtated that when the extenſion is properly managed, the reduction is effected almoſt ſpontaneouſly. Whatever may be the kind of primitive luxation, it is evident that the muſcles ſurrounding the articulation are on one ſide ſtretched, and on the other relaxed. Hence a change in their contractions, and in the direction of thoſe contractions, is neceſſarily occaſioned. This alteration is ſuch, that if the muſcles act, inſtead of pulling the head of the bone towards the lacerated capſule, they drag it in quite a contrary direction, and thus produce a conſecutive luxation.

But it is very different, when, by means of extenſion, the direction of the action of the muſcles has been rectified. They now tend to pull the head of the bone towards the ruptured capſule, and indeed they do ſo with much more certainty than the ſurgeon, who is always ignorant of the preciſe ſituation of the opening in the capſule. On the other hand, when the extenſion is ill made, and the natural direction of the muſcles has not been reſtored, the head of the bone is forced againſt another part of the capſule; and hence the difficulty of reduction ſo frequently experienced.

It follows from the preceding obſervations, firſt; that the whole ſkill in the treatment of luxations is to make the extenſion in an advantageous direction. Secondly; that, in general, what has been termed coaptation is almoſt always uſeleſs. Thirdly; that the reduction of a luxation does not conſiſt in putting the head of the bone into its cavity again; but in placing the muſcles in a ſtate in which they are enabled to reduce the bone.

But it is not to be denied that there are caſes where the action of the muſcles being perverted, in conſequence of the long exiſtence of the diſlocation, and the formation of adheſions to the ſurrounding parts, it becomes neceſſary to reſort to means for forcing, as it were, the paſſage of the head of the bone into the glenoid cavity.

When the luxation has been reduced, the arm is to be kept motionleſs for a few days, leſt the head of the bone ſhould ſlip out of its place again. Surgeons have been accuſtomed to apply the ſpica bandage, though without the leaſt reaſon, as it does no good whatſoever, becauſe it has no effect in confining the limb. The proper practice is to keep the arm quiet, and cloſe to the ſide with a roller and ſling. Deſault himſelf employed the bandage deſcribed in the article FRACTURE. See *Fracture of the Clavicle.*

Method adopted by Engliſh Surgeons.—In this country, ſurgical practitioners always reduce diſlocations of the ſhoulder while the patient is in a ſitting poſture, and, inſtead of imitating the French, they adhere to the ancient mode of applying the extending force to the luxated bone itſelf, juſt above the elbow. No doubt, they have been more influenced in ſuch practice by the authority of Mr. Pott, than by any real advantage attending the method. According to the notions of this latter gentleman, "all the force uſed in reducing the luxated head of a bone, be it more or leſs, be it by hands, towels, ligatures, or machines, ought always to be applied to the other extremity of the ſaid bone, and as much as poſſible to that only." Another maxim laid down by Pott is, that in order to make uſe of an extending force with all poſſible advantage, and to excite thereby the leaſt pain and inconvenience, it is neceſſary that all parts, ſerving to the motion of the diſlocated joint, or in any degree connected with it, be put into ſuch a ſtate as to give the ſmalleſt poſſible degree of reſiſtance.

"This (ſays Mr. Pott) I take to be the firſt and great principle by which a ſurgeon ought to regulate his conduct in reducing luxations. This will ſhew us why a knowledge of all the muſcular and tendinous parts, acting upon or in connection with the articulations, is abſolutely neceſſary for him who would do his buſineſs ſcientifically, with ſatisfaction to himſelf, or with eaſe to his patient. It will ſhew us that the mere poſition of the limb below the luxated joint, is what muſt either relax or make tenſe the parts in connection with that joint, and, conſequently, that poſture is more than half the buſineſs. It will ſhew us why ſometimes the luxated os humeri ſlips in, as it were of its own accord, by merely changing the poſition of the arm, when very violent attempts, previous to this, have proved ſucceſsleſs. It will ſhew us why extending the arm in a ſtraight line, horizontally, or ſo as to make a right angle with the body, muſt in ſome inſtances render all moderate attempts fruitleſs. Why the method of attempting reduction by the heel in the axilla is ſo often ſucceſsful, notwithſtanding two very conſiderable diſadvantages under which it labours; *viz.* part of the force being *loſt in the elbow*, and the tenſe ſtate of one head of the biceps cubiti. Why the tying down the fore-arm in the common ambi is wrong for the ſame reaſons. Why the fore-arm ſhould at all times (let the method of reduction be what it may) be bent; *viz.* becauſe of the reſiſtance of the long head of the biceps in an extended poſture. Why, when the os humeri is luxated forward, or ſo that its head lies under the great pectoral muſcle, the carrying of the extended arm backward, ſo as to put that muſcle on the ſtretch, renders the reduction very difficult; and why, on the contrary, the bringing the arm forward, ſo as to relax the ſaid muſcle, removes that difficulty, and renders reduction eaſy, &c."

In our opinion, ſome of theſe obſervations do not ſhew the thing intended, quite as well as Mr. Pott ſeems to conceive. We do not ſee how *all* the parts, in connection with a joint, can be relaxed by poſture. We ſee, it is true, how bending the elbow relaxes the biceps, but then it puts the long head of the triceps on the ſtretch, which may alſo reſiſt the reduction. As for the extending force being *loſt* in the elbow, when applied below the diſlocated bone, we have endeavoured to prove the error of the ſuppoſition in our general remarks. With reſpect to the laſt part of the foregoing, we think the explanation given by Bichat, in his edition of Deſault's works, more correct, namely, that when the luxated head of the humerus lies forward under the pectoral muſcle, carrying the elbow forwards and inwards tends to throw the head of the bone backwards and outwards, and then the muſcles are enabled to act with effect in promoting the reduction.

To the truth of the enſuing remarks, delivered by Mr. Pott, we have pleaſure in aſſenting. That in the reduction of ſuch joints as conſiſt of a round head moving in an acetabulum, or ſocket, no attempt ought to be made for replacing the ſaid head, until it has by extenſion been brought forth from the place where it is, and nearly to a level with the ſaid ſocket. This will ſhew us why the old method by the door, or ladder, ſometimes produced a fracture of the neck of the ſcapula, Mr. Pott himſelf has ſeen happen. Why, if a ſufficient degree of extenſion be not made, the towel, over the ſurgeon's ſhoulder, and under the patient's axilla, muſt prove an impediment rather than an aſſiſtance, by thruſting the head of the humerus under the neck of the ſcapula, inſtead of directing it into its ſocket. Why the common method of bending the arm, that is, the os humeri, downward, before ſufficient extenſion has been made, prevents the very thing aimed at, by puſhing the head of the bone under the ſcapula, which the continuation of the extenſion, for a few ſeconds only, would have carried into its proper place. When the head of the os humeri is drawn forth from the axilla, and brought to a level with the cup of the ſcapula, it muſt be a very great and very unneceſſary addition of extending force, that will, or can keep it from going into it. All that the ſurgeon has to do, is to bring it to ſuch a level; the muſcles attached to the bone will do the reſt.

A very juſt and important maxim, inculcated by Mr. Pott, and indeed by every judicious ſurgical writer of recent date, is, that whatever kind or degree of force may be found neceſſary for the reduction of a luxated joint, ſuch force be employed gradually; that the leſſer degree be always firſt tried, and that it be increaſed *gradatim.* See Pott's Remarks on Fractures and Diſlocations, vol. i. of his works.

After adverting to a few impediments to the reduction of diſlocated ſhoulders, we may here (not abruptly we hope) take leave of the ſubject, without expatiating on the methods purſued in this country, becauſe in fact the practice of Deſault, as already related, differs from our's chiefly in the extenſion being made at the wriſt. If we ſuppoſe the elbow bent, and the extending force applied juſt above the joint, it will be eaſy to follow the directions already given, with regard to the manner of making the extenſion, and the time and mode of altering the poſition of the bone during the proceſs.

We ſhall conclude our account of diſlocations of the ſhoulder, with noticing ſome circumſtances which may tend to render the reduction difficult.

The firſt to which we ſhall requeſt the reader's attention, is the narrowneſs of the lacerated opening in the capſular ligament. The practice of Deſault, when he had reaſon to ſuſpect this kind of impediment, was to endeavour to dilate the aperture by moving the humerus very freely and forcibly in every direction, and puſhing its head at the ſame time towards the glenoid cavity.

The luxation not being recent, may be another cauſe hindering the reduction, and is ſometimes an inſurmountable obſtacle to ſucceſs. The luxated head of the bone, after a time, contracts adheſions; and the ſurrounding cellular ſubſtance becomes condenſed, and converted as it were into a new kind of capſular ligament, which confines the bone in its unnatural ſituation. Moſt ſurgical authors recommend us in ſuch a caſe to make no endeavour to put the bone into its place again, as the attempt would, in all probability, fail, and might bring on ſerious conſequences, by reaſon of the violence which muſt be exerted. Deſault once profeſſed the ſame doctrine, but in the latter part of his life experience led him to a bolder practice. After being completely ſucceſsful in reducing ſome luxations, which had exiſted from fifteen to twenty days, he was encouraged to attempt the reduction of others, which had happened from thirty to five and thirty days; and during the two years before his death, he had, in Bichat's preſence, replaced diſlocations of the ſhoulder after ten weeks, and even three months, when the head of the humerus had eſcaped either at the inferior, or internal part of the capſule. Notwithſtanding the long continued extenſions which were employed, there were none of the terrible conſequences induced, with which authors have intimidated the generality of practitioners. In two inſtances, a ſudden and unaccountable emphyſema of the ſhoulder took place, which yielded to the uſe of a bandage and the ſaturnine lotion. See Œuvres de Deſault par Bichat, tom. i. p. 377.

In caſes of this kind, before the extenſion is begun, the bone ſhould be freely moved about in every poſſible direction, in order, in the firſt inſtance, to break the adheſions, lacerate the condenſed cellular ſubſtance, that ſerves as the accidental capſule, and thus produce, as it were, a ſecond luxation for the purpoſe of curing the firſt. The means for extenſion are then to be applied as uſual, with an increaſed number of aſſiſtants. In theſe caſes we have ſeen the multiplied pulley uſed with advantage, though it is certainly a dangerous machine, unleſs in careful hands.

Frequently the firſt attempts are unavailing, and the luxated head of the bone continues immoveable, in the midſt of the moſt powerful efforts. The extenſion is then to be ſtopped, and the bone moved about again in all directions; every reſiſtance is to be broken; let the arm deſcribe a large ſegment of a circle in the place which it occupies; and let it be rotated on its axis. Then let extenſion be repeated in every direction.

For caſes proving the occaſional efficacy of ſuch practice, we muſt refer to Deſault's Œuvres Chirurg. par Bichat, tom. i. p. 375.

In this excellent work it is obſerved that, ſuppoſing the attempts to fail, they are not entirely uſeleſs; for, by moving the head of the bone ſomewhat towards the glenoid cavity, or even juſt before it, they give the limb a greater freedom of motion.

A third obſtacle to the reduction of all luxations ariſes from the power of the muſcles, which power is exerted with violence in conſequence of the manner in which theſe organs are ſtretched. Sometimes the reſiſtance of the muſcles, indeed, abſolutely hinders the head of the bone from being at all moved, notwithſtanding the extenſion is very conſiderable. In ſuch a caſe, bleeding and the warm bath are to be tried, in order to bring on a temporary weakneſs and relaxation, during which the attempts at reduction may be made with the beſt proſpect of ſucceſs. But a ſtill more certain plan is long continued unremitting extenſion, which is ſure of fatiguing the reſiſting muſcles, and as ſoon as they are worn out, the bone may eaſily be replaced. Deſault in certain caſes did not ſucceed before the half, or even the whole of the day had been ſpent in keeping up the extenſion, by means of his apparatus for the broken clavicle, which apparatus draws outward the ſhoulder and alſo the muſcles. (See Fracture *of the Clavicle.*) The muſcles can only ſupport a violent contraction a certain time. To permanent extenſion, though moderate in degree, they cannot make long reſiſtance, they become fatigued, they are incapable of hindering the head of the bone from being moved in the deſired direction, and the reduction is accompliſhed.

We have ſeen that Mr. Pott and Deſault have particularly adverted to the difficulty of reduction, ariſing from the bone being preſſed againſt the neck of the ſcapula, when the elbow was depreſſed, before the extenſion had ſufficiently diſengaged the head. Mr. Hey has alſo noticed this obſtacle to reduction, as follows: "the difficulty of reducing a diſlocated humerus, not only ariſes from the reſiſtance or compreſſion of the muſcles; but alſo from the reſiſtance which is made by the preſſure of the glenoid proceſs againſt the neck of the humerus, when the head of the bone lies deep in the axilla beyond that proceſs. This hindrance to reduction will be increaſed in proportion to the depreſſion of the acromion; if the extenſion is made in a horizontal direction. For in this caſe the edge of the glenoid cavity pitches againſt the neck of the humerus, and, in ſome degree, prevents the head of the bone from advancing forwards. In order to remove this hindrance, the head of the humerus muſt be lowered by elevating the arm, and the edge of the glenoid cavity raiſed from the neck of the humerus by repreſſing the acromion." Mr. Hey then ſtates that he has now, for ſeveral years, preferred the method recommended by Mr. Bromfield, for repreſſing the acromion during the extenſion, and he inſiſts on the propriety of bending the fore-arm, before applying the means for extenſion, ſo that the biceps may be relaxed as much as poſſible, and not hinder the glenoid cavity from being repreſſed. See Practical Obſervations in Surgery, p. 299, 300. edit. 2. A deſcription of Bromfield's method may be found in this gentleman's Chirurgical Obſerv. and Caſes, vol. i. chap. 6. p. 269.

Luxations of the Elbow-joint, or of the Fore-arm from the Humerus.—Here authors have generally deſcribed four kinds of diſlocation; *viz.* backwards, forwards, outwards, and inwards; but all theſe caſes do not occur with equal frequency, as experience proves, and the ſtructure of the joint might enable us to anticipate.

The luxation of the bones of the fore-arm backwards are by far the moſt common; the diſlocation of them forwards is very rare, was never obſerved by Deſault or Petit, and indeed cannot happen without a fracture of the olecranon. Luxations inwards or outwards are alſo not frequent, and when they do happen they muſt almoſt inevitably be incomplete, in conſequence of the great extent of the articular ſurfaces. The frequency of luxations backwards, compared with that of lateral diſlocations, is eſtimated in Deſault's works by Bichat as 10 to 1. The luxation forward being ſo uncommon, no compariſon whatever is aſſigned. The coronoid proceſs, forming only an inconſiderable curvature, cannot make any vaſt reſiſtance to the aſcent of the olecranon and radius, up the poſterior part of the humerus. But the kind of hook which the olecranon makes, effectually hinders this proceſs itſelf as well as the radius from ſlipping forwards in front of the humerus. Indeed, as we have already obſerved, a luxation in this direction may be regarded as impoſſible, without a fracture of the olecranon. The lateral ligaments, and the reciprocal manner in which the irregular ſurfaces of the articulation fit each other, are alſo ſtrong obſtacles to lateral diſlocations. Luxations backwards are, as we have ſaid, by far the moſt frequent.

In the luxation backwards, the radius and ulna may aſcend more or leſs behind the humerus; but the coronoid proceſs of the ulna is always carried above the articular pulley, and is found lodged in the cavity deſtined to receive the olecranon. The head of the radius is placed behind and above the external condyle of the humerus. The annular ligament, which confines the ſuperior extremity of the radius to the ulna, may be lacerated; in which caſe, even when the bones are reduced, it is difficult to keep them in their proper places, as the radius tends conſtantly to ſeparate from the ulna.

This luxation always takes place from a fall on the hand; for, when we are falling, we are led by a mechanical inſtinct to bring our hands forwards to protect the body. If in this caſe the ſuperior extremity, inſtead of reſting vertically on the ground, be placed obliquely with the hand nearly in a ſtate of ſupination, the repulſion which it receives from the ground will cauſe the two bones of the fore-arm to aſcend behind the humerus, whilſt the weight of the body preſſing on the humerus, directed obliquely downwards, forces its extremity to paſs down before the coronoid proceſs of the ulna.

The fore-arm, in this luxation, is in a ſtate of half-flexion, and every attempt to extend it occaſions acute pain. The ſituation of the olecranon, with reſpect to the condyles of the humerus, is changed. The olecranon, which in the natural ſtate is placed on a level with the external condyle, which is itſelf ſituated lower than the internal, is even higher than the latter.

This luxation may be miſtaken for a fracture of the olecranon, of the head of the radius, or even of the inferior extremity of the humerus. Such a miſtake is attended with very bad conſequences; for if the reduction be not effected before the end of fifteen or twenty days, it is often impoſſible to accompliſh it afterwards. The ſwelling, which ſupervenes in twenty-four hours after the accident, renders a diagnoſis more difficult; but the olecranon and internal condyle are never ſo obſcured, that the diſtance between them cannot be found to be increaſed, though Boyer makes a contrary aſſertion. It is true, that the rubbing of the coronoid proceſs and olecranon againſt the humerus, may cauſe a grating noiſe, ſimilar to that of a fracture; and ſome attention is certainly requiſite to eſtabliſh a diagnoſis between a fracture of the head of the radius, and a diſlocation of the fore-arm backwards.

The following method of reducing the caſe is adviſed by Boyer:—The patient being firmly ſeated, an aſſiſtant is to take hold of the middle part of the humerus, and make the counter-extenſion, while another aſſiſtant makes extenſion at the inferior part of the fore-arm. The ſurgeon, ſeated on the outſide, graſps the elbow with his two hands, by applying the fore-fingers of each to the anterior part of the humerus, and the thumbs to the poſterior, with which he preſſes on the olecranon, in a direction downwards and forwards. This method will be in general ſucceſsful. If the ſtrength of the patient, or the long continuance of the luxation, render it neceſſary to employ a greater force, a fillet is to be applied on the wriſt, to make extenſion, and a cuſhion is to be placed in the axilla, and the arm and trunk fixed, as is done in caſes of luxation of the humerus.

A bandage may afterwards be applied, in the form of a figure of 8, and the arm is to be kept in a ſling. The laceration which always takes place, is always followed by more or leſs ſwelling, which is to be combated by antiphlogiſtic means.

At the end of ſeven or eight days, when the inflammatory ſymptoms are nearly gone, the articulation is to be gently moved, and the motion is to be increaſed every day, in order to prevent an anchyloſis, to which there is a great tendency.

In this luxation, the annular ligament which confines the head of the radius to the extremity of the ulna, is ſometimes torn, and the radius paſſes before the ulna. In ſuch caſes, pronation and ſupination are difficult and painful, though the principal luxation has been reduced. The head of the radius may be eaſily replaced, by preſſing it from before backwards, and it is to be kept in its place by a compreſs, applied to the ſuperior and external part of the fore-arm. The bandage and compreſſes are to be taken off every two or three days, and re-applied. This is neceſſary, on account of the neceſſity of moving the articulation to prevent an anchyloſis.

If the luxation be not ſoon reduced, it becomes irreducible; the heads of the radius and ulna grow to the back part of the humerus, and the patient can neither bend nor extend his arm. However, in ſome caſes, eſpecially in young perſons, ſome motion is acquired in time; the heads of the radius and ulna making in the humerus cavities, in which they perform ſome motions, but always imperfectly.

The luxation forwards ſhould be treated as a fracture of the olecranon, with which it would be inevitably accompanied. It may be neceſſary, on account of the great injury done to the ſoft parts, to bleed the patient copiouſly, and put him on an antiphlogiſtic regimen.

As to the lateral luxations, either inwards or outwards, they are always incomplete, and eaſily diſcovered. They are reduced by drawing the humerus and fore-arm in contrary directions, and at the ſame time puſhing the extremity of the humerus, and the two bones of the fore-arm in oppoſite directions.

Theſe luxations cannot be produced without conſiderable violence; but when the bones are reduced, they are eaſily kept in their place. It will be ſufficient to paſs a roller round the part, to put the fore-arm in a middle ſtate, neither much bent nor extended, and to ſupport it in a ſling. But much inflammation is to be expected from the injury done to the ſoft parts. In order to prevent it, or at leaſt mitigate it, the patient is to be bled two or three times, and put on a low diet, and the articulation is to be covered with the lotio aq. litharg. acet. It is ſcarcely neceſſary to repeat, that the arm is to be moved as ſoon as the ſtate of the ſoft parts will admit of it.

The diſlocation of the fore-arm backward, is ſaid to occur ten times as frequently as lateral luxations; and thoſe forward are ſo rare, that no compariſon whatever can be drawn. Œuvres Chir. de Deſault, tom. i.

Lateral luxations have been divided into *complete*, that is, when the articular ſurfaces have entirely loſt their ſtate of reciprocal contact; and into *incomplete*, that is, when only one bone, or a part of it, is thrown off the humerus. But what cauſe can operate with ſufficient force to produce the firſt occurrence? The miſchief would alſo be ſo great, were ſuch a caſe to happen, that amputation would moſt likely be requiſite.

The incomplete lateral luxation may be produced by a blow, which drives the upper part of the fore-arm violently outward, or inward. A footman, ſays Petit, in falling from a coach, had his arm entangled in the ſpokes of a wheel, and a diſlocation outward was the conſequence. Another man luxated his fore-arm inward, by falling from his horſe and driving his arm againſt an uneven place.

When the ulna is puſhed into the ſituation of the radius, the ſpace between the olecranon and internal condyle is much greater than is natural. Theſe points of bone are always very diſtinguiſhable, let the joint be ever ſo much ſwollen; and hence, the information to be derived from an examination of them, may be obtained in every caſe, without exception. Alſo, when the ulna is puſhed into the place of the radius, the latter bone cannot be eaſily rotated, nor can the fore-arm be bent and extended in a perfect manner.

The diſlocation inward muſt be very uncommon, as the form of the bones is almoſt an inſurmountable obſtacle to ſuch an accident. It may happen, however, as the authority of Petit confirms.

All recent diſlocations of the elbow are very eaſily reduced, and as eaſily maintained ſo; for the reciprocal manner in which the articular ſurfaces receive each other, and their mutual eminences and cavities, will not readily allow the bones to become diſplaced again.

The application of a bandage in the form of a figure of 8, and ſupporting the arm in a ſling, are proper in all theſe caſes.

Luxation of the Radius from the Ulna.—The majority of authors, who have written on diſlocations of the fore-arm, have not ſeparately conſidered thoſe of the radius. Some detached obſervations, on luxations of its ſuperior extremity, are to be found here and there; a ſubject which Duverney alone has fully treated of. The diſlocations of its lower end, which are more frequent, and eaſy of occurrence, have almoſt eſcaped the notice of French, and alſo Engliſh writers. At preſent, caſes of this ſort have been ſo numerouſly collected, that a particular account of them may be offered.

Difference of Structure, between the two Joints of the Radius with the Ulna.—The radius, the moveable agent of pronation and ſupination, rolls round the ulna, which forms its immoveable ſupport, by means of two articular ſurfaces; one above, ſlightly convex, broad internally, narrow outwardly, and correſponding to the little ſigmoid cavity of the ulna, in which it is lodged; the other below, concave, ſemi-circular, and adapted to receive the convex edge of the ulna. Hence there are two joints, differing in their motions, articular ſurfaces, and ligaments. By aſcertaining ſuch differences, we ſhall be enabled to find out thoſe which exiſt between the luxations of the upper and lower head of the radius.

Above, the radius, in pronation and ſupination, only moves on its own axis; below, it rolls round the axis of the ulna. Here, being more diſtant from the centre, its motions muſt be both more extenſive and powerful than they are above. The head of the radius, turning on its own axis in the annular ligament, cannot diſtend it in any direction. On the contrary, below, the radius, in performing pronation, ſtretches the poſterior part of the capſule, and preſſes it againſt the immoveable head of the ulna, which is apt to be puſhed through, if the motion be forced. A ſimilar event, in a contrary ſenſe, takes place in ſupination. The front part of the capſule, being rendered tenſe, may now be lacerated.

Add to this diſpoſition, the difference of ſtrength between the ligaments of the two joints. Delicate and yielding below; thick and firm above; their difference is very great. The upper head of the radius, ſupported on the ſmaller immoveable articular ſurface of the ulna, it protected from diſlocation in moſt of its motions. On the contrary, its lower end, carrying along with it in its motions the bones of the carpus which it ſupports, cannot itſelf derive any ſolid ſtability from them.

Differences of Luxations of the Radius.—From what has been ſaid, the following concluſions may be drawn: 1, that with more cauſes of luxation, the lower articulation of the radius has leſs means of reſiſtance; and, that under the triple conſideration of motions, ligaments tying the articular ſurfaces together, and the relations of theſe ſurfaces to each other, this joint muſt be very ſubject to diſlocation. 2. That, for oppoſite reaſons, the upper joint cannot be very ſubject to ſuch an accident.

Indeed what could be the cauſe producing it in this ſituation? Can it ariſe from a violent pronation, or ſupination? The lower joint being the weakeſt would give way the firſt, and however forcible any motion of this kind might be, the upper head of the radius would only be rotated on its own axis. How then can this part be diſlocated without being puſhed forward or backward? All the muſcular and ligamentous ſupport of the joint muſt be broken; and the muſcles and ligaments are too ſtrong to admit of this, and the motion itſelf too feeble. Can the accident originate from any impulſe on the radius, from below upward? The immoveable reſiſting end of the humerus would then prevent the radius from quitting the capſular ligament. Can the accident ariſe from a violent extenſion or flexion of the fore-arm? Here, the whole force operating on the ulna, the radius ſcarcely feels the impulſe.

Hence, accidental diſlocations of the radius, ſuddenly produced by an external cauſe, muſt, if they ever happen, be exceedingly uncommon at its upper end. This is not the caſe with reſpect to ſuch diſlocations which occur ſlowly at this joint, eſpecially in children, in whom the ligaments become lax in conſequence of repeated efforts. With this kind of caſe, we have here nothing to do.

Experience ſometimes ſeems to militate againſt the above reflections. Duverney quotes ſome inſtances of diſlocations of the radius, ſuddenly produced by external cauſes. Some other practitioners mention ſimilar examples. But, in their examinations, have theſe men paid all due attention? An analogous caſe has been tranſmitted to the French Academy of Surgery, by one of its fellows; but doubts have ariſen concerning its reality, and there are too few facts for, and too much preſumptive evidence againſt, the truth of ſuch caſes to believe their exiſtence. Deſault himſelf rejected their reality.

Luxation of the lower End of the Radius.—The cauſes are the ſame as thoſe of all analogous caſes. 1. Violent action of the pronator and ſupinator muſcles. This is, doubtleſs, a very unuſual cauſe, for Deſault never knew an inſtance of it. 2. External force, moving the radius violently into a ſtate of pronation, and rupturing the back part of the capſule; or into a ſtate of ſupination, and breaking the front part of the capſular ligament.

Hence, there are two kinds of diſlocation; one forward, the other backward. The firſt is very frequent; the ſecond is much leſs ſo. The latter caſe never preſented itſelf to Deſault but once, in the dead body of a man who had both his arms diſlocated, and no particulars could be learnt. The other caſe occurred very often in the practice of this eminent ſurgeon. Five examples have been publiſhed. Doubtleſs, this difference is owing to all the principal motions of the radius being in the prone direction.

This obſervation is confirmed by the fact, that the lower joint of the radius, in the dead ſubject, may be diſlocated as eaſily by a ſupine, as a prone motion of this bone.

The ſymptoms of the luxation forward are: 1. Conſtant pronation of the fore-arm. 2. An inability to perform ſupination, and great pain on this being attempted. 3. An unuſual projection at the back of the joint, in conſequence of the protruſion of the little head of the ulna through the capſule. 4. The poſition of the radius is more forward than natural. 5. Conſtant adduction of the thumb, which alſo is almoſt always extended. 6. A half-bent ſtate of the fore-arm, and very often of the fingers. This, indeed, is the poſition which the fore-arm uſually aſſumes in all affections of its bones, and, in the preſent inſtance, the poſture cannot be changed without conſiderable pain. 7. More or leſs ſwelling around the joint. This ſometimes comes on immediately after the accident, but always afterwards, if the reduction ſhould remain unaccompliſhed. The condition of the joint may thus be obſcured, and the accident miſtaken for a ſprain; as Deſault often obſerved to have occurred with ſurgeons, who had been called to theſe accidents before him. The ſerious conſequence of this miſtake is, that no attempt at reduction is made, and the articular ſurfaces having time to contract adheſions, the diſorder is frequently rendered irremediable.

A luxation of the radius backward is characterized by ſymptoms the reverſe of thoſe above-mentioned. They are a violent ſupination of the limb; inability to put it prone; pain on making the attempt; a tumour in front of the fore-arm formed by the head of the ulna; a projection backward of the large head of the radius; and abduction of the thumb.

Reduction.—When the diſlocation is forward, an aſſiſtant is to take hold of the elbow, raiſing the arm a little from the body; another is to take hold of the hand and fingers.

The ſurgeon is to take hold of the end of the fore-arm with both his hands; one applied to the inſide, the other to the outſide, in ſuch a manner, that the two thumbs meet each other before, between the ulna and radius, while the fingers are applied behind. He is then to endeavour to ſeparate the two bones from each other, puſhing the radius backward and outward, while the ulna is held in its proper place. At the ſame time the aſſiſtant, holding the hand, ſhould try to bring it into a ſtate of ſupination, and conſequently the radius, which is its ſupport. Thus puſhed, in the direction oppoſite that of the diſlocation, by two powers, the radius is moved outward, and the ulna returns into the opening of the capſule, and into the ſigmoid cavity.

If chance ſhould preſent a diſlocation of the radius backward, the ſame kind of proceeding, executed in the oppoſite direction, would ſerve to accompliſh the reduction.

Luxations of the Wriſt.—The carpal bones may be luxated from the lower ends of the radius and ulna forwards, backwards, inwards, or outwards. The two firſt caſes, eſpecially the one backwards, are the moſt frequent. The diſlocation backwards is rendered eaſy by the direction of the convex articular ſurfaces of the ſcaphoid, ſemilunar, and pyramidal bones, which ſloping more backwards than forwards, muſt make them more diſpoſed to ſlip in this direction than any other. The accident may be cauſed by a fall on the back of the hand, while much bent; in which event the firſt row of the carpal bones ſlide backwards into the oblong cavity of the radius, lacerate the poſterior ligament, and form an eminence behind the lower ends of the bones of the fore-arm. This prominence, the depreſſion in front of the wriſt, and the extraordinary flexion of the hand, which cannot be extended, are the characteriſtic ſigns of this kind of diſlocation.

The diſlocation forwards generally ariſes from a fall on the palm, the fingers being extended, and more force operating on the lower than upper part of the palm. The luxation is ſeldom complete; and the hand remains painfully extended. The great many tendons, which run before the wriſt, and the annular ligament being puſhed forward, the prominence formed by the carpal bones, in front of the ends of the radius and ulna, is not eaſily detected, and the caſe may be miſtaken for a ſprain.

Diſlocations inwards, or outwards, are never complete. The projection of the carpal bones at the inner or outer ſide of the joint, and the diſtortion of the hand, make ſuch caſes ſufficiently evident.

All diſlocations of the wriſt are very eaſy of reduction. For this purpoſe, gentle extenſion muſt be made, while the two ſurfaces of the joint are made to ſlide on each other in a direction contrary to what they took when the accident occurred.

Diſlocations of the wriſt are always attended with a great deal of ſpraining of numerous tendons and laceration of ligaments, and conſequently conſiderable ſwelling generally follows, and the patient is a long time in regaining the perfect uſe of the joint. To relieve the ſymptoms as much as poſſible, the beſt plan is to keep the hand and wriſt continually covered with linen wet with the ſaturnine lotion, and to put the fore-arm and hand in ſplints, as in the caſe of a fracture. (See FRACTURE.) The arm muſt alſo be kept perfectly at reſt in a ſling.

When the ruptured ligaments have united, the uſe of liniments will tend to remove the remaining ſtiffneſs and weakneſs of the joint.

Luxations of the Bones of the Carpus and Metacarpus.—A diſlocation of the carpal bones from each other ſeems almoſt impoſſible. The os magnum, however, has been known to be luxated from the deep cavity formed for it by the ſcaphoides and ſemilunare, in conſequence of too great a flexion of the bones of the firſt phalanx on thoſe of the ſecond, and it forms a tumour on the back of the hand. Chopart. Boyer. Richerand.

The metacarpal bones are never luxated from each other. The firſt one is ſometimes, though very rarely, puſhed off the trapezium.

Luxations of the Fingers.—The firſt phalanges may be diſlocated backwards off the heads of the metacarpal bones. A luxation forwards would be very difficult, if not impoſſible, becauſe the articular ſurfaces of the metacarpal bones extend a good way forwards, and the palm of the hand makes reſiſtance to ſuch an accident. The firſt phalanges of the thumb and little finger can alone be diſlocated inwards; and the firſt phalanx of the thumb is alone ſubject to be luxated outwards. This phalanx is alſo moſt liable to diſlocations backwards, behind the head of the firſt metacarpal bone, in which caſe it remains extended, while the ſecond is bent.

Theſe diſlocations ſhould be ſpeedily reduced; for, after eight or ten days, they become irreducible. In a luxation of the firſt bone of the thumb, which was too old to be reduced, Deſault propoſed cutting down to the head of the bone, and puſhing it into its place with a ſpatula. Diſlocations of the thumb and little finger inwards, that of the thumb outwards, and luxations of the firſt phalanges of the other fingers backwards, are all reduced by making extenſion on the lower end of the affected thumb, or finger. The firſt and ſecond phalanges may alſo be diſlocated backwards.

After the reduction, the thumb or finger affected ſhould be rolled with tape, and incaſed, and ſupported in paſteboard, till the lacerated ligaments have united; taking care to keep the hand and fore-arm quietly in a ſling.

Luxations of the Femur, or Thigh-bone, at the Hip.—Theſe diſlocations may take place upwards and outwards on the exernal ſurface of the os ilium; upwards and forwards on the body of the os pubis; downwards and inwards on the foramen ovale; and downwards and outwards on the os iſchium.

The luxation upwards and outwards, and that downwards and inwards, are the moſt frequent, and it is not eaſy to ſay which of theſe two caſes happens moſt often. It is to be underſtood, however, that diſlocations of the hip are far leſs common than thoſe of the ſhoulder. We have ſeen only three caſes of the firſt deſcription; but, at leaſt, from fifteen to twenty diſlocations of the ſhoulder. Mr. Hey informs us, that ſeven inſtances of the latter accident, and three of the former, are all that have occurred in his practice. (Pract. Obſ. p. 314. edit. 2.) The following account of luxations of the thigh-bone at the hip is from Boyer's work on the Diſeaſes of the Bones, tranſl. by Farrell.

No anatomical reaſon can be given for the frequency of the diſlocation upwards and outwards; the edge of the acetabulum projects more at the ſuperior and exterior parts than at any other; the orbicular ligament, which is very thick at this place, and the interior ligament of the articulation, which muſt be previouſly ruptured, oppoſe the diſlocation in this direction. There is little, on the contrary, to oppoſe the luxation downwards on the foramen ovale. The inferior and internal part of the circumference of the cavity, the place by which the bone eſcapes in this ſpecies of luxation, preſents a deep notch formed into a hole by a ligament, under which the veſſels of the articulation enter. The orbicular ligament is thinner here than at any other place; the motion of abduction, in which this luxation takes place, is more extenſive than that of adduction; and laſtly, the round ligament within the articulation does not oppoſe it, as it may take place without its being ruptured.

Luxation upwards and forwards is very rare; that downwards and backwards is ſtill more ſo; and, perhaps, as ſhall be obſerved farther on, never occurs but ſecondarily.

When, by a fall from a place more or leſs elevated, on the ſoles of the feet, or on the knees, the thigh is puſhed forwards and inwards, the head of the femur, forced towards the ſuperior and external part of the acetabulum, breaks the internal and orbicular ligaments, eſcapes through the laceration in the latter, and aſcends on the external face of the os ilium; but as the part of the os ilium immediately above and at the external ſide of the cavity is very convex, the head of the femur ſoon abandons its firſt poſition, and ſlides backwards and upwards into the external foſſa of the os ilium, following the inclination of the plane towards this foſſa, and obeying the action of the glutæi muſcles, which draws it in this direction. The head of the femur, in aſcending thus on the external face of the os ilium, puſhes upwards the glutæus minimus, which forms a ſort of cap for it; and the glutæus maximus and medius are relaxed by the approximation of the points into which they are inſerted. The pyriformis is nearly in its natural ſtate, the gemini, obturatores, and quadratus femoris, are a little elongated. The pſoas magnus and iliacus internus are relaxed, as are alſo the other muſcles inſerted into the trochanter minor. If to this deſcription it be added, that the orbicular ligament, torn at its ſuperior part, is ſtretched over the acetabulum, and covers it, an exact idea may be formed of the change occaſioned in the ſurrounding parts by this luxation of the femur.

The affected thigh is ſhorter than the ſound one; it is a little bent, and carried inwards. The knee inclines more forwards and inwards than the oppoſite one; the leg and thigh are turned inwards, and the foot points in this direction. The trochanter major is brought nearer the anterior and ſuperior ſpinous proceſs of the os ilium, and is at the ſame time elevated and carried a little forwards; the latter circumſtance may be conſidered as the neceſſary conſequence of the rotation inwards of the thigh. The natural length of the limb cannot be reſtored without reducing the luxation; the foot cannot be turned outwards, and any attempt to do ſo cauſes pain; but the inclination of the foot inwards may be increaſed. If the patient endeavours to walk, he extends the foot to put the top of it on the ground; and though the heel is raiſed, he is ſtill lame; for the diſeaſed limb remains always ſhorter than the other, and the pain occaſioned by the attempt to walk renders progreſſion ſtill more difficult.

Luxation of the femur upwards and outwards has nothing in common with the fracture of the neck of this bone but the ſhortneſs of the limb. The eaſy rotation of the member outwards and inwards, &c. &c. preclude all poſſibility of confounding them, unleſs the ſurgeon be remarkably inattentive.

It is difficult to aſſign the cauſe of the foot and remainder of the limb being turned inwards in this luxation. It may be eſtabliſhed as a general rule, that luxated members always take a direction determined by the elongation of the muſcles of the ſide oppoſite that to which the luxated bone is carried: thus, in luxation of the arm downwards and inwards, the deltoides and infraſpinatus muſcles, lengthened by the ſeparation of their points of inſertion, move the elbow out from the body, and give the arm an oblique direction. In this caſe, the obturatores, gemini, and quadratus femoris, being elongated, the point of the foot ought to be turned outwards. This phenomenon depends perhaps on the external portion of the orbicular ligament which comes from the anterior and inferior ſpine of the os ilium; this portion, which is very thick, being elongated in the luxation outwards, draws the great trochanter forwards, and conſequently turns inwards the entire limb.

The difficulty of reducing luxations of the thigh, from the ſtrength and number of its muſcles, renders every diſlocation of which it is ſuſceptible very diſtreſſing. The laceration and injury done to the ſoft parts are nearly as conſiderable as in diſlocation of the ginglimoidal articulations.

To effect the reduction, the patient is extended on a table firmly fixed, and covered with a mattreſs, which is to be tied to it; a ſheet, folded longitudinally, is applied to the groin of the ſound ſide, in order to make counter-extenſion. The middle part is applied againſt the ſuperior and internal part of the thigh, and the two ends paſſed before and behind the pelvis, croſs on the hip, and are held by a ſufficient number of aſſiſtants. By this means the trunk is fixed, but there is nothing to prevent the pelvis from yielding to the extending force. To anſwer this purpoſe, another ſheet, folded in a ſimilar manner, is placed tranſverſely on the ſpine of the os ilium, and its ends are brought horizontally before and behind the abdomen towards the hip of the oppoſite ſide, where they are held by aſſiſtants. This apparatus, ſimilar to that placed on the point of the ſhoulder in a luxation of the arm, anſwers the ſame purpoſes, as it preſſes only on the ſuperior part of the glutæus maximus and medius, and does not ſtimulate them to contract. The extending force is to be applied to the inferior part of the leg, in order to have it as far as poſſible from the parts which reſiſt the return of the head of the femur. The number of aſſiſtants for making extenſion and counter-extenſion is to be proportioned to the exigencies of the circumſtances and the power of muſcles. The ſurgeon, placed at the external ſide of the limb, preſſes on the great trochanter, and when the head of the bone has been brought on a level with the acetabulum, he endeavours to force it into it.

In this country, as we have previouſly explained, ſurgeons generally apply the extenſion to the diſlocated bone itſelf, juſt above the knee. The diſappearance of all the ſymptoms, and eſpecially the noiſe made by the head of the femur on re-entering its cavity, indicate the ſucceſs of the operation. This ſucceſs is ſeldom obtained without having previouſly made ſeveral fruitleſs endeavours, whether from not employing ſufficient force to make extenſion and counter-extenſion, or from a ſpaſmodic contraction of the muſcles obſtinately reſiſting the reduction.

When the bone is reduced, it is prevented from leaving its place by bringing the thighs together by means of a bandage placed above the knees. In the generality of caſes, it will be adviſable to take ſome blood from the patient, and confine him for a few days after the accident to a very low diet; and in all caſes the hip is to be covered with emollient and reſolvent applications, which may be kept on by means of the ſpica bandage for the groin. This bandage is well adapted to this uſe, but is not at all fit for keeping the luxated bone in its proper place, as its action is made too near the centre of motion. The patient ſhould be particularly directed not to walk too ſoon, nor at any time to fatigue too much the affected joint.

Luxation of the thigh downwards and inwards, or into the foramen ovale, is nearly as frequent as that juſt deſcribed; it is favoured, as we have ſaid, by the great extent of the motion of abduction of the thigh; by the notch at the inferior and internal part of the acetabulum; by the weakneſs of the orbicular ligament at this ſide; and laſtly, by the ſituation of the round ligament, the rupture of which is not a neceſſary conſequence of it. It is occaſioned by a fall on the feet or knees conſiderably ſeparated from one another. The head of the femur ſlides from without inwards on the bottom of the acetabulum, and comes againſt the inferior and internal portion of the orbicular ligament, which it lacerates, and paſſes on to the foramen ovale between the ligament and the obturator externus.

In this ſpecies of luxation of the femur, the ſtate of the ſoft parts ſurrounding the articulation is as follows: the glutæi, gemini, obturatores, quadratus femoris, pſoas magnus, and iliacus internus, are elongated by the ſeparation of their points of inſertion. The rotation of the limb outwards is produced by the elongation of theſe muſcles. The adductors, elongated, form at the interior part of the thigh a tenſe cord, which is felt from the pubis to below the middle of the thigh.

The affected thigh is longer than the ſound one; the head of the femur being placed lower than the acetabulum, the great trochanter is removed to a greater diſtance from the anterior and ſuperior ſpinous proceſs of the os olium, and the thigh is flattened in conſequence of the elongation of the muſcles. The adductors, extended obliquely from the pubis to the femur, form a cord which elevates the ſkin of the internal part of the thigh. A hard round tumour is felt at the inner and ſuperior part of the thigh, formed by the head of the femur, which elevates the ſoft parts ſituated before the foramen ovale. The leg is ſlightly bent; the knee and foot, turned outwards, cannot be brought back to their proper direction. If the patient attempt to walk a few ſteps, he makes a ſemicircular motion with the foot, and places at once the entire ſole on the ground; and though he keep the knee bent, ſtill the limb is too long, and occaſions lameneſs. The mode of progreſſion of perſons whoſe thigh is luxated in this direction may be compared to that of a mower: the elongated extremity, like the leg which the mower keeps forwards, deſcribes a ſemicircular motion outwards.

All theſe ſymptoms, taken together, form a combination too ſtriking to admit of error in our diagnoſis, or to allow us to confound this luxation with any other, or even with fracture of the neck of the femur.

The prognoſis is ſomewhat leſs unfavourable in this than in luxation upwards and outwards. The muſcles, which might oppoſe the reduction, being all elongated by the very circumſtance of the luxation itſelf, render the reduction eaſier; beſides, the contuſion of the ſoft parts is leſs conſiderable, and the round ligament is ſtretched, but not broken. It is reduced in the ſame manner as the other, except that the extenſion is to be made at firſt downwards and outwards, before bringing the limb to its natural direction.

Luxation upwards and forwards is much rarer than the preceding, and more than one practitioner has deſcribed it rather as poſſible than as having abſolutely taken place. It has been alſo called luxation on the pubis, though it may be reaſonably preſumed that the head of the femur is removed

moved ſo far from the acetabulum but in very few caſes, and that it only advances near the ilio-pectinæal eminence. Deſault met with a luxation of this kind in a porter of the flour-market; his foot ſlipped, and the leg and thigh were carried backwards, whilſt a heavy burden was placed on his ſhoulders. His body was bent backwards, and the head of the femur, directed forwards and upwards, burſt its capſule and triangular ligament, and paſſed under the crural arch into the fold of the groin, where it was eaſily felt through the integuments.

The whole extremity is turned outwards in this luxation; it is alſo ſhortened. The great trochanter, brought nearer the anterior and ſuperior ſpinous proceſs of the os ilium, is placed before that eminence; that part into which the pſoas and iliacus muſcles are inſerted is raiſed up, and a tumour is formed by the head of the femur in the fold of the groin, which compreſſes more or leſs the crural nerves placed at the external ſide of the veſſels of this name, and occaſions dull pains, with numbneſs and even paralyſis, when the contuſion has been very great; the knee, turned outwards, is alſo carried backwards. This ſymptom is particularly remarkable ſhortly after the accident has taken place; for if the diſlocation has continued ſome days, the thigh may reaſſume its natural direction, and perform even gentle rotatory motions inwards, the direction outwards ſtill continuing. It is proper to remark, with reſpect to the tumour formed by the head of the femur in the groin, that the pſoas and iliacus muſcles may, in fractures of the femur immediately under the little trochanter, bring forwards the ſuperior portion of this bone, cauſe it to project in the groin, and form an eminence there which might impoſe on us, if we were not apprized of the poſſibility of ſuch an event taking place.

This luxation is particularly dangerous, as it requires a combination of violent efforts to produce it, and as it neceſſarily muſt be accompanied with great contuſion and lacerations. Neverthele∫s, in the caſe treated by Deſault, the reduction, though difficult, was not followed by any ſerious accident; and the patient, at the end of fifteen days, had almoſt entirely recovered the ſtrength and uſe of his limb.

The proceſs for reducing it does not differ from that pointed out for the others.

Luxation of the femur downwards and backwards may, like that of the humerus inwards and forwards, be either primary or ſecondary. It is primary, when, in conſequence of ſome effort, the head of the femur is forced from the acetabulum at its inferior and poſterior part, and is placed at the junction of the os ilium and iſchium; it is ſecondary, when it ſucceeds to the luxation upwards and outwards, the head of the femur, which was placed at firſt in the external iliac foſſa ſliding downwards and backwards, its paſſage in this direction being favoured by the bending of the thigh on the pelvis.

In theſe two caſes, the head of the femur reſts againſt that part of the oſſa innominata where the os ilium and iſchium join. The muſcles which cover the poſterior part of the articulation, ſuch as the pyriformis, gemini, obturatores, and quadratus femoris, are raiſed up and ſtretched; the pſoas magnus and iliacus internus are in a great ſtate of tenſion, and this explains the turning of the limb outwards. When this luxation is primary, the extremity is lengthened; a hard tumour is felt at the poſterior and inferior part of the thigh; the great trochanter, by deſcending, is removed farther from the ſpine of the os ilium, and the knee and ſole of the foot are turned outwards; but if it be ſecondary, the thigh is much bent againſt the pelvis; the knee and ſole of the foot are turned inwards, becauſe the primary luxation has been upwards and outwards. Secondary luxation in this direction is much more frequent than the primary; in reducing it the ſame rules are to be obſerved as in other ſpecies of luxations.

Whatever may be the ſpecies of luxation, we ſhould always be certain that it is perfectly reduced before leaving the patient. To aſcertain this, we ought to move the thigh in various directions, taking care at the ſame time to omit that motion which might reproduce the luxation.

When a luxation of the femur upwards and outwards has not been reduced, the thigh remains ſhort, and becomes ſhorter every day, until the head of the femur has made for itſelf a kind of articular cavity in the ſurface of the external iliac foſſa. The acetabulum leſſens in ſize, or is entirely obliterated. The glutæus minimus is emaciated, and ſerves as an orbicular ligament to the new articulation. The head of the femur loſes its ſpherical figure, is forced backwards, and its neck becomes ſhorter; the perſon is lame, and walks on the point of the foot. If the luxation is downwards and inwards, the foramen ovale becomes the new articulating cavity; the obturator externus, raiſed and puſhed inwards by the head of the femur, becomes emaciated and ligamentous, and it and the glutæus minimus even ſometimes oſſify. The lameneſs ariſes in this caſe from the exceſs of length of the diſeaſed limb, which always diminiſhes in ſize, in conſequence of the muſcles not being ſufficiently exerciſed, or their action being impeded.

Luxations of the Patella, or Knee-pan.—It is impoſſible for the patella to be diſlocated downwards without the tendon of the extenſor muſcles of the leg being firſt ruptured; nor upwards, unleſs the ligament of the patella is broken. In this laſt caſe the extenſor muſcles may draw the bone more or leſs upwards towards the groin.

Diſlocations inwards, or outwards, may happen without other miſchief. They occur when the patella is violently puſhed in one of theſe directions. According to Boyer, great relaxation of the inferior ligament of the patella may create a prediſpoſition to the accident. Such, ſays he, was the caſe of the young man, whoſe patellæ were luxated outwards by the ſlighteſt motion of the knees, as related by Hard in the Journ. de. Méd.

The diſlocation outwards is the moſt common. This may depend partly on the internal edge of the patella projecting more than the external one, and, therefore, being more expoſed to violence; and partly, on the outer condyle of the thigh-bone allowing the patella to ſlip over it with facility.

Boyer obſerves, that the external condyle of the femur, which is naturally more eminent anteriorly than the inner one, may be depreſſed, and this depreſſion, from whatever cauſe it may proceed, favours the diſlocation outwards. He tells us that he has ſeen, among the military conſcripts, three caſes of luxation of the left patella outwards from ſuch a cauſe. In theſe three individuals the patella was placed at the outſide of the condyle, though not altogether away from it. The anterior ſurface of the bone was turned outwards; the poſterior one inwards; the internal edge was placed anteriorly, and projected under the ſkin, while the external edge was directed backwards. In all theſe inſtances the luxation had taken place during infancy. By relaxing the extenſors of the leg, and bending the thigh, the patella could eaſily be replaced; but unleſs confined in its proper ſituation, it was ſoon diſlocated again.

Another caſe is recorded by the ſame writer, where a luxation of the patella outwards followed a gunſhot-wound, in the vicinity of the knee.

Luxations outwards, produced by external violence, are rarely complete, as ſuch an accident could only ariſe from a degree of force that is hardly ever exerted. The diſlocation is much promoted by the knee being, at the time of the blow, in a moderate ſtate of flexion, as the extenſor muſcles of the leg and ligament of the patella are then relaxed, and the inner edge of the patella very prominent, ſo as to be expoſed to the action of external force.

In luxations of the patella outwards, the patient experiences ſevere pain, and cannot bend his knee. The latter joint is deformed; the pulley of the condyles of the femur may be felt through the ſkin; the patella forms a tumour in front of the external condyle; the anterior ſurface of the knee-pan is become the external one, while the poſterior ſurface is now internal. The internal edge is turned more forwards than inwards, and the external one is now turned almoſt quite backwards.

The ſymptoms of a luxation inwards are very analogous to thoſe of the preceding caſe, allowance being made for the difference of ſituation and the relation of parts to each other.

In every caſe of diſlocated patella, the reduction ſhould be effected as ſoon as poſſible. The patient is to be laid on a bed, with his leg extended and thigh bent. In this poſition the extenſor muſcles and their tendon, and the ligament of the patella, are relaxed, and the latter bone may eaſily be put back into its proper ſituation by preſſure.

The inflammatory ſwelling, which uſually affects after an accident of this nature, is to be ſubdued by general and topical bleeding, reſt, and the ſaturnine lotions. After the ſwelling and inflammation are diminiſhed, the joint ſhould be gently bent and extended every day, and rubbed with the linimentum ſapon. comp.

Luxations of the Knee.—The tibia, at its articulation with the condyles of the femur, may be luxated either backwards, forwards, or to either ſide.

A complete luxation of the knee is an exceedingly uncommon circumſtance, and could not happen without a total laceration of all the numerous ligaments and tendons which ſtrengthen the joint. For the production of ſuch miſchief, we muſt ſuppoſe the operation of a degree of violence that hardly ever takes place, putting out of the queſtion the tearing away of limbs by cannon-balls. Even incomplete luxations, inwards or outwards, are very rare, ſo much are theſe accidents oppoſed by the extent of the articular ſurfaces, and the ſtrength of the ligaments and tendons. Diſlocations forwards or backwards are ſtill more uncommon, in conſequence of the manner in which the patella and crucial ligament reſiſt their occurrence. However, when the leg is fixed, and the body and thigh are forced onwards, the tibia may be partly forced away from the lower end of the femur to one ſide or another. The accident implies the operation of conſiderable violence. The deformity makes the nature of the caſe very manifeſt. The reduction is eaſily accompliſhed by puſhing the heads of the bones in oppoſite directions, while the articular ſurfaces are a little ſeparated by moderate extenſion of the limb. After the reduction, the main buſineſs of the ſurgeon is to avert and diminiſh inflammation of the joint by cold waſhes, leeches, veneſection, opening medicines, low diet, perfect reſt, &c.

Luxations of the Ankle Joint.—The foot may be luxated inwards, or outwards; or forwards, or backwards; and the diſlocation in any of theſe directions may be complete or incomplete. Luxations inwards or outwards, are the moſt frequent. The former, however, are more common than the latter. As the internal malleolus does not deſcend ſo far as the external, the aſtragalus has a leſs ſpace to deſcribe from without inwards, than in the contrary direction. The diſlocation inwards is occaſioned by a violent abduction of the foot, and is characterized by the ſole being turned outwards, and the back of the foot inwards, by the pain and inability of moving the foot; and, laſtly, by the projection made by the aſtragalus below the internal malleolus.

The luxation outwards is attended with an impoſſibility of moving the foot; the ſole is turned inwards and the back of the foot outwards; and the aſtragalus projects below the external malleolus.

All luxations of the foot ſhould be reduced as quickly as poſſible. One aſſiſtant is to make the counter-extenſion by fixing the leg, and, while another draws the foot, the ſurgeon is to puſh the latter part in a direction contrary to that in which it is luxated. Nothing facilitates the reduction of diſlocations of the ankle ſo materially as relaxing the powerful muſcles of the calf of the leg, by bending the knee and extending the foot.

When the reduction has been accompliſhed, the limb is to be put in ſplints, juſt as if the caſe were a fracture of the leg, (ſee Fracture,) and the antiphlogiſtic treatment is indicated for the prevention of violent inflammation.

Theſe caſes, in former days, generally ended ſo badly, that J. L. Petit recommends amputation never to be delayed more than twenty-four hours after the accident. More modern experience, however, has proved the general poſſibility of curing diſlocations of the ankle, and this even when the caſe is compound, that is, attended with a wound communicating with the injured point.

A fracture of the fibula near its lower end is a frequent complication of a luxation of the foot inwards. That bone, therefore, ſhould always be carefully examined in the latter caſe.

Luxations forwards and backwards, leſs frequent than thoſe deſcribed, are however ſometimes met with. The firſt is occaſioned by a fall backwards while the foot is fixed to the ground; the ſecond by a fall on the feet, with the body inclined forwards and the leg much bent. The luxation forwards is more difficultly produced than that backwards, on account of the articular pulley of the aſtragalus, which inclines towards the poſterior ſide, being permitted to ſlide much on the tibia without abandoning it in the extenſion of the foot. When the extenſion is carried too far, luxation forwards is produced.

In the luxation backwards, the external and poſterior ligaments and the poſterior part of the capſule are torn; in that forwards the anterior and external ligaments, the anterior fibres of the internal lateral ligament, and the anterior part of the capſule, are torn. The ſymptoms of the firſt ſpecies are, a diminution of length in that part of the foot between the lower part of the leg and the anterior extremity of the toes, elongation of the heel, tenſion of the tendo Achillis, and relaxation of the extenſors of the toes. It is impoſſible either to bend or extend the foot; this ſymptom diſtinguiſhes luxation from ſprain, in which the foot may be moved, though not without pain, however high the inflammation may be.

Contrary ſymptoms accompany the luxation forwards: the foot is lengthened, the heel is ſhortened, and the foot, much extended, cannot be bent, &c.

The reduction of both is eaſily effected, after which it will be neceſſary to put the limb in ſplints, and lay it in the bent poſture.

The very thick and ſhort ligamentous ſubſtance which unites the aſtragalus to the os calcis, binds them ſo ſtrongly together, that they follow one another in their motions and form, as it were but one bone. Hence they are never completely ſeparated, even in the moſt deſperate caſes of luxation of the foot; but one or both of them may be luxated from the ſcaphoides and cuboides. The tranſverſe direction of the articulation formed by theſe four bones, ſuggeſted to Chopart the ingenious idea of amputating only a part of the foot. But theſe luxations, leſs dangerous than the others, can be occaſioned only by a violent effort in which the anterior part of the foot is fixed, as happened in the two caſes related by J. L. Petit, the foot being faſtened in an iron grate, whilſt the body was drawn backwards. The aſtragalus and os calcis may, under theſe circumſtances, be luxated, but particularly the former, the head of which ſlides from below upwards, in the cavity of the poſterior face of the ſcaphoides, and forms a tumour on the back of the foot. The inflammatory ſwelling renders it often difficult to aſcertain this luxation. It is not eaſily reduced, even ſhortly after it has taken place. Boyer failed in a caſe of this kind in which the head of the aſtragalus was luxated upwards and inwards by a fall from a horſe; but in ſome time the perſon felt no inconvenience from the affection, he could walk without pain or lameneſs, and nothing remained but the deformity occaſioned by the tumour.

The other bones of the tarſus and metatarſus are too ſtrongly tied together to admit of luxation. The phalanges of the toes cannot be luxated by external violence, on account of their ſhortneſs. However, the poſſibility of luxation of the firſt phalanx of the great toe from the firſt bone of the metatarſus may be eaſily conceived. See Boyer on the Bones, vol. ii.

Compound Luxations.—We ſhall conclude the preſent article with a few remarks on the treatment of compound diſlocations. The luxation of a large joint, being conjoined with an external wound, leading into the capſular ligament, is a circumſtance that has a particular tendency to increaſe the danger of the accident. In many caſes we ſee injuries of this deſcription followed by violent and extenſive inflammation, abſceſſes and ſloughing, fever, delirium, and death. When the patient is advanced in years, is much debilitated, or of an unhealthy irritable conſtitution, compound luxations, eſpecially if attended with much contuſion and other injury of the ſoft parts, and wrongly treated, very often have a fatal termination. This, however, is not the general event of theſe caſes, and whatever may have happened in former times, we now know, that in the preſent improved ſtate of ſurgery ſuch accidents moſtly admit of cure. We would not, however, by any means inſinuate cenſure againſt every inſtance of amputation performed in theſe caſes: we know that ſuch operation is occaſionally indiſpenſable immediately when the accident is ſeen, and we are equally aware, that it may become neceſſary in a future ſtage, when extenſive abſceſſes or ſloughing, joined with threatening conſtitutional ſymptoms, have occurred. Our only deſign is to recommend the endeavour to cure the generality of compound luxations. But if a caſe were to preſent itſelf, attended with very great contuſion and laceration of the ſoft parts, we ſhould be as earneſt advocates for amputation as any practitioners.

The treatment of a compound diſlocation requires the reduction to be effected without delay, and with as little violence and diſturbance as poſſible. The limb is then to be placed in ſplints, with the requiſite pads, eighteen-tailed bandage, &c. The wound is to be freed from any dirt or extraneous matter, and its lips accurately brought into contact with ſtrips of adheſive plaſter. The joint is to be covered with linen wet with the ſaturnine lotion, the bandage is to be looſely laid down, and the ſplints faſtened on with their proper ſtraps or pieces of tape, and the limb is to be kept perfectly at reſt in an eligible poſture. The patient, if ſtrong and young, is to be bled. This laſt practice may be more freely adopted in the country than in London, or large hoſpitals. Purging, however, muſt never be omitted, and an anodyne, the firſt night or two, will be highly proper. Saline draughts, antimonials, and a low regimen, are alſo indicated during the firſt few days of the ſymptomatic fever which commonly follows ſo ſerious an accident.

If the caſe takes a favourable courſe, the conſtitutional indiſpoſition will not be exceſſive, nor will the pain and inflammation of the limb be immoderate. Sometimes the wound even unites, more or leſs, without ſuppuration, a circumſtance of the higheſt importance, as tending more than any thing to leſſen the danger, by changing the caſe, as it were, from a compound into a ſimple one. In other caſes, the wound is not united, but the inflammation and ſuppuration are not violent or extenſive, and there is every reaſon to expect ultimate ſucceſs. When the wound is diſpoſed to unite favourably, lint and adheſive plaſter are the beſt dreſſings. In other inſtances, while the ſuppuration is at all copious, or the inflammation high or extenſive, emollient poultices are moſt eligible.

When the ſymptomatic fever and firſt inflammatory ſymptoms are over, and there is much diſcharge, attended with marks of approaching weaking, the patient is to be allowed more food, and be directed to take bark, cordials, porter. wine, &c. If his nights are reſtleſs, he muſt have opiates; and, in ſhort, all ſuch medicines as his particular complaints may require, are to be preſcribed.

When the inflammation of a compound diſlocation is violent or extenſive, general bleeding, and the uſe of leeches, are the moſt effectual means of counteracting the miſchief.

In certain caſes, the moſt ſkilful treatment is unavailing. The joint and limb become affected with conſiderable pain and ſwelling; the fever runs high; delirium comes on; and the patient may even periſh from the violence of the firſt ſymptoms, the limb being generally at the ſame time attacked with gangrene. If theſe firſt dangers are avoided, the wound may not heal favourably; the inflammation may be extenſive; large abſceſſes under the faſciæ may be formed; and the hectical ſymptoms and ſinking ſtate of the patient may make the only chance of recovery depend upon amputation. But even this operation is ſometimes deferred till too late, and the patient muſt be left to his miſerable fate.

Whoever gives the ſmalleſt reflection to the nature of compound fractures, will perceive, that it is often a matter of the laſt importance to make a right deciſion at the very beginning, whether amputation ſhould be immediately done, or whether an attempt to ſave the limb ought to be made. In ſome inſtances, the patient's ſole chance depends upon the operation being performed at once without the leaſt delay, and the opportunity of doing it never returns.

Thus, when great inflammation and a rapid mortification of the limb follow the accident, the patient may die before the ſloughing has ſhewn the leaſt inclination to ſtop.

But, beſides this firſt critical period, the ſurgeon often has to exerciſe a nice degree of judgment in a future ſtage of the caſe; we mean when the ſuppuration is copious, and the health much impaired. Here the practitioner may err in taking off a limb that might be ſaved; or he may commit a worſe fault, and make the patient loſe his life in a fruitleſs attempt to ſave the member. No precepts can form the right practitioner in this delicate part of ſurgery; genius alone cannot do it; we would add, mere experience, however great, cannot do it: the opportunity of making obſervations, and the talent of profiting by them, are here the things which make the conſummate ſurgeon.

LUXEMBOURG, Francis Henry de Montmorency, *Duke of*, in *Biography*, a celebrated French general, ſon of the count of Boutteville, who was beheaded under Lewis XIII. for fighting a duel, was born in 1628. He was educated for the military profeſſion, and at the age of fifteen was, at the battle of Rocroi, under the illuſtrious Condè, whoſe various fortunes he followed. He reſembled that hero in ſeveral of his qualities, and was himſelf admitted a duke and peer of France. In 1667, he was promoted to a lieutenant-generalſhip, and in that character he was, in the following year, active in the conqueſt of Franche-Comtè. He had the chief command, in 1672, in the invaſion of Holland, where, in one campaign, he took a number of towns, and gained the battles of Bodegrave and Woerden: after this, he made a famous retreat with an army of 20,000 men, againſt 70,000. In 1675, he was oppoſed to the prince of Orange, and by his ſucceſs obtained the dignity of marſhal of France. In 1690, he gained the battle of Fleurus, which was followed by ſeveral other very important victories. Previouſly to theſe laſt-named ſucceſſes he had been detained a priſoner in the Baſtile more than a year, on charges connected with his amours, to which, notwithſtanding the deformity of his perſon and features, he was much addicted. He died in 1695, and with him, it has been ſaid, terminated the victories and grandeur of Lewis XIV. No general after him poſſeſſed, to ſo high a degree, the attachment and confidence of the ſoldiers. His uniform ſucceſs, when contending with king William, rendered him an object of jealouſy to that prince, who once, in the bitterneſs of his heart, called him a "hump-back;" "What does he know of my back," ſaid the marſhall, "he never ſaw it?" Moreri.

LUXEMBURG, in *Geography*, one of the ten Catholic provinces of the Netherlands before the French revolution, bounded on the north by the biſhopric of Liege, and duchies of Limburgh and Juliers, on the E. by the electorate of Treves, and on the S. and W. by France; to which, by a late treaty, it is now annexed, conſtituting, in part, the department of the *Forêts;* which ſee. It lies in the centre of the foreſt of Ardennes. Its ſoil, though not fertile, produces ſome corn; but it furniſhes a good breed of cattle, wine, all ſorts of game, iron-works, and founderies for cannon, which are the chief ſource of its wealth. It is watered by many ſmall rivers which run into the Meuſe and Moſelle. It contains, beſides the city of Luxemburg, 23 other ſmaller towns.

Luxemburg, a city of France, principal place of a diſtrict, and capital of the department of the Forêts. From being a caſtle, built by the people of Treves, it was enlarged by the Romans, and called "Auguſta Romanorum." When Merovinus, king of France, conquered the country, it was called the "city of the ſun," becauſe the ſun was anciently adored there, as the moon was at Arlon, Jupiter at Ivoy, now called Carignan, and Mars at Marche en Famine. This city is ſmall, but ſtrong, on account both of its ſituation and fortifications, which were thought to be the ſtrongeſt in Europe. It is divided by the river Alſitz, which runs through it, into the Upper and Lower Towns; the former being ſituated on a rock, the latter in a plain. Its number of inhabitants is eſtimated at about 10,000, its two cantons contain 20,522, on a territory of 247½ kiliometres, in 14 communes. Having frequently changed maſters, being at one time in the poſſeſſion of France, at another time in that of Spain, again under the dominion of the States-General, to which it was ceded by the barrier treaty in 1701, and afterwards, *viz.* in 1715, poſſeſſed by the emperor; it was blockaded by the French, after they had acquired by arms the ſurrounding country, and ſurrendered to them on the 7th of June, 1795, by capitulation. The ſurrender of Luxemburg put the French in poſſeſſion of the whole country on the left of the Rhine, except Mentz; 50 miles S.S.E. of Liege. N. lat. 49° 40′. E. long. 6° 13′.

LUXEUIL, a town of France, in the department of the Upper Saône, and chief place of a canton, in the diſtrict of Lure; 14 miles N.E. of Veſoul. The place contains 3080, and the canton 13,261 inhabitants, on a territory of 190 kiliometres, in 27 communes. N. lat. 47° 49′. E. long. 6° 27′.

LUXOR, Luxorein, or *Akſor*, a village of Egypt, on the right ſide of the Nile, the ſcite of which is the ruins of the celebrated city of *Thebes*, which ſee. Of theſe ruins we ſhall now only mention from Mr. Browne's Travels (p. 135.), that they extend for about three leagues in length along the Nile. Eaſt and weſt they reach to the mountains, a breadth of about 2½ leagues. The river is here about 300 yards broad. The circumference of the ancient city muſt, therefore, have been about 27 miles. This ingenious traveller is of opinion that Luxor and Akſor are corruptions of El Kuſſur, the real term, which is ſtill applied to the ruins by the Arabs; 18 miles S. of Kous.

LUXURIANT Plants, a term in *Gardening*, ſignifying ſuch as become greatly augmented in growth beyond their common natural ſtate, and which rarely acquire that degree of perfection which is the caſe with thoſe of more moderate growths. This ſometimes happens from the exceſs of nouriſhment, and ſometimes from the nature of the plants.

But it is produced differently; ſometimes prevailing in the whole plant, ſometimes in particular parts, as in ſome of the ſhoots, and frequently in the flowers.

The firſt of theſe may be conſidered ſuch as ſhoot much ſtronger than plants of the ſame ſpecies generally do, and it happens both in herbaceous plants and trees, &c. which never attain perfection ſo ſoon as the more moderate growers: thus, many ſorts of eſculent plants, which ſhoot luxuriantly to leaves and ſtalks, &c. as cucumbers, melons, cabbages, cauliflowers, turnips, radiſhes, beans, peas, &c. never arrive ſo ſoon to perfection as thoſe of moderate growth; and ſuch plants as appear to be naturally of themſelves of a very luxuriant nature, are very improper to ſtand, from which to ſave ſeed for future increaſe.

And this is alſo the caſe in fruit-trees; as ſuch as are very luxuriant ſhooters are much longer before they attain a bearing ſtate than thoſe of middling growth, and they never bear ſo plentifully, or have the fruit attain ſuch perfection. This luxuriance is frequently acquired by unſkilful pruning, eſpecially in wall-trees, &c. as it is often the practice, when wall or eſpalier trees aſſume ſuch a growth, to cut all the ſhoots ſhort; by which, inſtead of reducing the tree to a moderate ſtate of ſhooting, it has its vigour increaſed, as too conſiderable ſhortening of ſtrong ſhoots promotes their throwing out ſtill ſtronger, and producing more abundant or ſuperfluous wood. Therefore, in pruning very luxuriant eſpalier and wall-fruit trees, they ſhould be aſſiſted ſomewhat in their own way, as it were, by training in plenty of ſhoots annually for a year or two, to divide the redundancy of ſap; or, in the ſummer and winter prunings, always leaving them rather thicker than in the common practice, and moſtly at full length, unleſs it be neceſſary to ſhorten ſuch as are of very conſiderable length, or in ſome particular part of the tree, to force out a ſupply of wood to fill a vacancy. Some ſorts of fruit-trees ſhould, indeed, never be generally ſhortened in the common courſe of pruning, except in caſual, very extended, irregular growths, or occaſionally for procuring a ſupply of wood, as mentioned above. This is particularly neceſſary in apples, pears, plums, cherries, and fig-trees; for, if generally ſhortening was to be practiſed in theſe ſorts, they would continue ſhooting every year ſo luxuriantly to wood, that they would never form themſelves into a proper bearing ſtate: even in thoſe trees where ſhortening is neceſſarily practiſed in winter, in moſt of the annual ſupplies of ſhoots, as in peaches, nectarines, &c. in caſes of luxuriant growth, it ſhould be very ſparingly performed, the general ſhoots not being cut very ſhort, and ſome of the moſt vigorous left almoſt or quite at the full length. This is the proper method to reduce luxuriant trees to a moderate growth, and to a bearing ſtate; as by training the ſhoots thicker, and leaving them longer, and continuing it for a year or two, the redundant ſap, having greater ſcope to divide itſelf, cannot break out with that luxuriance as when it has not half the quantity of wood to ſupply with nouriſhment, as in the caſe of ſhort pruning. See ESPALIER, WALL-TREES, and PRUNING.

This ſtate ſeldom occurs with any continuance in ſtandard-trees, where permitted to take their natural growth, except in caſual ſtraggling ſhoots, which ſhould always be taken out. Over-luxuriant ſhoots are moſtly met with in trees and ſhrubs; but require more particularly to be attended to in the culture of the fruit-tree kind, eſpecially thoſe of the wall and eſpalier ſort, which undergo annual pruning.

They are ſuch as ſhoot ſo vigorouſly in length and ſubſtance, as greatly to exceed the general growth of thoſe uſually produced on the ſame kind of plant or tree, and are ſometimes general, but in other caſes only happen to particular ſhoots in different parts of a tree, &c. They are diſcoverable by their extraordinary length and thickneſs, and by their vigour of growth, which always greatly impoveriſhes the other more moderate ſhoots in their neighbourhood, and likewiſe the fruit, &c. as well as often occaſions a very irregular growth in the reſpective trees. Such ſhoots frequently occur in wall and eſpalier fruit-trees, and are the effects of injudicious pruning. When they are in general wholly ſo, they ſhould be managed as directed above; but when only in particular ſhoots here and there in a fruit tree, or other tree or ſhrub under training, ſuch ſhoots being of ſuch a very luxuriant nature as to draw away the nouriſhment, at the expence of the adjacent moderate ſhoots, and which, by their vigorous irregular growth, cannot be trained with any degree of regularity; they ſhould for the moſt part, as ſoon as diſcoverable, in the ſummer or winter prunings, be cut out, taking them off as cloſe as poſſible to the part of the branch whence they originate, that no eye may be left to ſhoot again; unleſs ſuch a ſhoot ſhould riſe in any part of a tree or ſhrub, where a further ſupply of wood may be requiſite; in which caſe it may be retained and ſhortened as convenient, to force out a ſupply of more ſhoots laterally to fill the vacancy.

Where it prevails in other trees and ſhrubs than thoſe of the fruit kind, they ſhould have occaſional attention, pruning them in regular order in their younger advancing growth, or afterwards occaſionally in particular ſorts, as may be neceſſary: obſerving, in either, when any ſtraggling ſhoots, &c. aſſume a very luxuriant rambling growth, greatly exceeding the other general branches, that they may be more or leſs reduced or cut entirely away cloſe to their origin, as may be moſt expedient, according to the nature of growth of the trees or ſhrubs, either in ſummer or winter, &c.

Moſt double flowers may be conſidered as luxuriant, eſpecially ſuch as have the cup or corolla multiplied, or ſo augmented in the number of their leaves or flower-petals inward, as to exclude ſome part of the fructification, as the ſame thing occurs in flowers as in eſculent plants and fruit-trees, from their over-luxuriant growth; for, as the flower is deſigned for perfecting the fruit and ſeed, when the petals are multiplied to the diminution of the ſtamina, &c. no impregnation enſues, and of courſe no fruit or ſeed is produced.

In the double varieties of moſt kinds of flowers produced on ornamental flowering plants, this luxuriance is generally conſidered as a ſuperior degree of perfection; and has different modifications.

The higheſt degree of this ſort of luxuriance is met with in carnations, anemones, ranunculuſes, the poppy, lychnis, peony, narciſſus, violet, and ſome others.

LUXURY, ſays Mr. Hume, (Eſſ. vol. i. p. 285.) is a word of an uncertain ſignification, and may be taken in a good as well as a bad ſenſe. In general, it means great refinement in the gratification of the ſenſes; and any degree of it may be innocent or blameable, according to the age, or country, or condition of the perſon. The bounds between the virtue and the vice cannot here be exactly fixed, more than in other moral ſubjects. To imagine, that the gratifying of any ſenſe, or the indulging of any delicacy in meat, drink, or apparel, is of itſelf a vice, can never enter into a head, that is not diſordered by the frenzies of enthuſiaſm. "I have, indeed," ſays our author, "heard of a monk abroad, who, becauſe the windows of his cell opened upon a noble proſpect, made a *covenant with his eyes* never to turn that way, or receive ſo ſenſual a gratification." Such is the crime of drinking Champagne or Burgundy, preferably to ſmall beer or porter. Theſe indulgences are only vices, when they are purſued at the expence of ſome virtue, as liberality or charity; in like manner as they are follies, when for them a man ruins his fortune, and reduces himſelf to want and beggary. When they entrench upon no virtue, but leave ample ſubject whence to provide for friends, family, and every proper object of generoſity or compaſſion, they are entirely innocent, and have in every age been acknowledged ſuch by almoſt all moraliſts. To be entirely occupied with the luxury of the table, for inſtance, without any reliſh for the pleaſures of ambition, ſtudy, or converſation, is a mark of ſtupidity, and is incompatible with any vigour of temper or genius. To confine one's expence entirely to ſuch a gratification, without regard to friends or family, is an indication of a heart deſtitute of humanity or benevolence. But if a man reſerve time ſufficient for all laudable purſuits, and money ſufficient for all generous purpoſes, he is free from every ſhadow of blame or reproach. Since luxury may be conſidered either as innocent or blameable, one may be ſurpriſed, ſays Mr. Hume, at thoſe prepoſterous opinions which have been entertained concerning it; while men of libertine principles beſtow praiſes even on vicious luxury, and repreſent it as highly advantageous to ſociety; and on the other hand, men of pure morals blame even the moſt innocent luxury, and repreſent it as the ſource of all the corruption, diſorders, and factions incident to civil government. This author endeavours to correct both theſe extremes, by proving, 1ſt, that the ages of refinement are both the happieſt and the moſt virtuous; and 2dly, that wherever luxury ceaſes to be innocent, it alſo ceaſes to be beneficial; and when carried a degree too far, is a quality pernicious, though perhaps not the moſt pernicious to political ſociety. In proof of the firſt point he conſiders the effects of refinement both on *private* and *public* life. For his reaſoning we muſt refer to the Eſſay, above cited. Induſtry, knowledge, and humanity, ſays our author, are linked together by an indiſſoluble chain, and are found, from experience as well as reaſon, to be peculiar to the more poliſhed, and, what are commonly denominated, the more luxurious ages. He adds, that theſe advantages are not attended with any diſadvantages that bear any proportion to them. The more men refine upon pleaſure, the leſs will they indulge in exceſſes of any kind; becauſe nothing is more deſtructive to true pleaſure than ſuch exceſſes. Beſides, induſtry, knowledge, and humanity diffuſe their beneficial influence beyond the ſphere of *private* life, on the *public*, and render the government as great and flouriſhing as they make individuals proſperous and happy. Our author concludes his Eſſay on "Refinement in the Arts," with the following obſervations. "Luxury, when exceſſive, is the ſource of many ills; but is in general preferable to ſloth and idleneſs, which would commonly ſucceed in its place, and are more hurtful both to private perſons and to the public. When ſloth reigns, a mean uncultivated way of life prevails amongſt individuals, without ſociety, without enjoyment. And if the ſovereign, in ſuch a ſituation, demands the ſervice of his ſubjects, the labour of the ſtate ſuffices only to furniſh the neceſſaries of life to the labourers, and can afford nothing to thoſe who are employed in the public ſervice."

An excellent writer, to whom we ſhall next refer, takes occaſion, from a conſideration of the mode of living which actually obtains in any country, to illuſtrate the true evil and proper danger of luxury. Luxury, as it ſupplies employment and promotes induſtry, aſſiſts population. But it is attended with a conſequence, which counteracts and often overbalances theſe advantages. When, by introducing more ſuperfluities into general reception, luxury has rendered the uſual accommodations of life more expenſive, artificial, and elaborate; the difficulty of maintaining a family, conformbly with the eſtabliſhed mode of living, becomes greater, and what each man has to ſpare from his perſonal conſumption proportionably leſs: the effect of which is, that marriages become leſs frequent, agreeably to the maxim, which lies at the foundation of this reaſoning, that men will not marry to *ſink* their place or condition in ſociety, or to forego thoſe indulgences, which their own habits, or what they obſerve amongſt their equals, have rendered neceſſary to their ſatisfaction. This principle is applicable to every article of diet and dreſs, to houſes, furniture, and attendance; and this effect will be felt in every claſs of the community. For inſtance, the cuſtom of wearing broad cloth and fine linen repays the ſhepherd and flax-grower, feeds the manufacturer, enriches the merchant, gives not only ſupport but exiſtence to multitudes of families: hitherto, therefore, the effects are beneficial: and were theſe the only effects, ſuch elegancies, or, if they may be ſo called, ſuch luxuries, could not be too general. But here follows the miſchief: when once faſhion hath annexed the uſe of theſe articles of dreſs to any certain claſs, to the middling ranks, for example, of the community, each individual of that rank finds them to be *neceſſaries* of life; that is, finds himſelf obliged to comply with the example of his equals, and to maintain that appearance which the cuſtom of ſociety requires. This obligation creates ſuch a demand upon his income, and withal adds ſo much to the coſt and burthen of a family, as to put it out of his power to marry, with the proſpect of continuing his habits or of maintaining his place and ſituation in the world. We ſee, in this deſcription, ſays our author, the cauſe which induces men to waſte their lives in a barren celibacy; and this cauſe, which impairs the very ſource of population, is juſtly placed to the account of luxury. It appears, upon the whole, to be the tendency of luxury to diminiſh marriages, and that in this tendency the evil of it reſides. Hence it may be inferred, that of different kinds of luxury, thoſe are the moſt innocent which afford employment to the greateſt number of artiſts and manufacturers; as thoſe, in other words, in which the price of the work bears the greateſt proportion to that of the raw material. Thus, luxury in dreſs, in furniture, is univerſally preferable to luxury in eating, becauſe the articles which conſtitute the one, are more the production of human art and induſtry, than thoſe which ſupply the other. We may alſo conclude, that it is the *difference*, rather than the *degree*, of luxury, which is to be dreaded as a national evil. The miſchief of luxury conſiſts in the obſtruction that it forms to marriage. But, as it is only a ſmall part of the people in any country that is compoſed by thoſe of higher rank, the facility, or the difficulty, of ſupporting the expence of their ſtation, and the conſequent increaſe or diminution of marriages among them, will have but little influence on the ſtate of population. As long as the prevalence of luxury is confined to a few of elevated rank, much of the benefit is felt, and little of the inconvenience. But when the imitation of the ſame manners deſcends, as it always will do, into the maſs of the people; when it advances the requiſites of living beyond what it adds to men's abilities to purchaſe them, then it is that luxury checks the formation of families, in a degree that ought to alarm the public. To all which we may add, that the condition moſt favourable to population is that of a laborious, frugal people, miniſtering to the demands of an opulent, luxurious nation; becauſe this ſituation, while it leaves them every advantage of luxury, exempts them from the evils which naturally accompany its admiſſion into any country. Paley's Princ. of Mor. and Pol. Philoſ. vol. ii.

In our country there was formerly a multitude of penal laws intended for reſtraining exceſs in apparel; chiefly made in the reigns of Edward III., Edward IV., and Henry VIII., againſt piked ſhoes, ſhort doublets, and long coats, all of which were repealed by ſtatute 1 Jac. I. c. 25. Exceſs of diet, which is one ſpecies of luxury, is ſtill prohibited by 10 Edward III. ſtat. 3, which ordains that no man ſhall be ſerved at dinner or ſupper with more than two courſes: except upon ſome great holidays there ſpecified, in which he may be ſerved with three. See Sumptuary *Laws*.

LUYTS, John, in *Biography*, a philoſopher and aſtronomer, was born in North Holland in 1665. He became profeſſor of philoſophy and mathematics at Utrecht, where he died in 1721. He wrote 1. An Aſtronomical Work, in which he rejected the Copernican ſyſtem, entitled "Inſtitutio aſtronomica in qua doctrina ſphærica, atque theorica, intermixto uſu ſphæræ cœleſtis, et variis chronologicis, pertractantur." 2. An Introduction to Modern and Ancient Geography, with many plates. In all that he wrote and taught he ſhewed himſelf a great partiſan of the Ariſtotelian philoſophy, in oppoſition to that of Deſcartes. Moreri.

LUZ, La, in *Geography*, a ſea-port town of the iſland of Canary; five miles N. of Civdad de los Palmas.—Alſo, a town of France, in the department of the Higher Pyrenées, and chief place of a canton, in the diſtrict of Argeles. The place contains 2135, and the canton 6222 inhabitants, on a territory of 552½ kiliometres, in 17 communes.

LUZARA, a town of Italy, in the department of Mincio; 16 miles S. of Mantua.

LUZARCHES, a town of France, in the department of the Seine and Oiſe, and chief place of a canton, in the diſtrict of Pontoiſe; 5 leagues N. of Paris. The place contains 1696, and the canton 11,411 inhabitants, on a territory of 180 kiliometres, in 22 communes. N. lat. 49° 7′. E. long. 2° 30′.

LUZECH, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Cahors; 2½ leagues from Cahors. The place contains 2049, and the canton 10,504 inhabitants, on a territory of 162½ kiliometres, in 12 communes. N. lat. 44° 29′. E. long. 1° 23′.

LUZERATH, a town of France, in the department of the Rhine and Moſelle, and chief place of a canton, in the diſtrict of Coblentz. The place contains 614, and the canton 2525 inhabitants, in 12 communes.

LUZERNE, a large county of Pennſylvania, bounded north by Tioga county in New York, eaſt and ſouth-eaſt by Northampton, weſt by Lycoming and Northumberland counties; about 79 miles in length from north to ſouth, and 75 in breadth from eaſt to weſt, divided into 19 townſhips, and containing 2 churches, 33 ſaw-mills, 24 griſt-mills, 2 fulling-mills, and 1 oil-mill. The number of inhabitants is 12,839. Near the Suſquehannah river, which, with its tributary ſtreams, well waters it, the ſoil is very fertile, and produces good crops of wheat, flax, and hemp. The northern parts abound with pine, timber, and ſugar-maple. In the townſhips of Wilkſbarre, Kingſton, Exeter, and Plymouth, are large beds of coal. Coal and bog-iron are found in ſeveral places, and two forges have been erected. In this county are many remains of ancient fortifications, which are of an elliptical form, and covered with large white oak-trees. Its chief town is Wilkſbarre.

LUZIOLA, in *Botany*, Juſſ. 33. An annual Peruvian graſs, which Dombey took for a *Zizania*. It is deſcribed by Juſſieu as monœcious, without any calyx; the corolla of two valves, without awns. Male flowers in a looſe terminal ſpike. Stamens uſually eight, ſometimes nine or ten; anthers ſtalked. Female flowers panicled, inferior, much ſmaller. Styles two. Seed ovate, naked.

LUZULA, a genus eſtabliſhed by Decandolle in his edition of Lamarck's *Flore Françaiſe*, v. 3. 158; and adopted by Mr. R. Brown, Prodr. Nov. Holl. v. 1. 591. It conſiſts of ſuch Linnæan *Junci* as have a capſule of a ſingle cell, with only three ſeeds, as is the caſe with *J. campeſtris*, Linn. (Juncoides; Mich. Gen. 41. t. 31.) Whether the ſmall number of the ſeeds be a ſufficient character, ſeems to us at beſt doubtful, conſidering how various their number is in other *Junci*. The capſule having one cell or three is certainly of no importance, in either the three-ſeeded or many-ſeeded ſpecies; ſome having perfect partitions from the centre of their valves, others more or leſs of a ridge there in the place of them. The capſule of *Juncus Forſteri*, Engl. Bot. t. 1293, for inſtance, which by the number of its ſeeds ſhould be a *Luzula*, has a capſule of three cells. It is indeed much to be wiſhed, that plants ſo unlike the habit of moſt *Junci* could, by any ſound character, be ſeparated from them; but without ſuch they are beſt as they are.

LUZURIAGA, ſo called by the authors of the Flora Peruviana, in honour of a Spaniſh botaniſt, or patron of the ſcience, of the ſame name. Ruiz et Pavon Fl. Peruv. Brown Prodr. Nov. Holl. v. 1. 281.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Aſphodeli*, Juſſ. *Aſphodeleæ*, Brown.

Eſſ. Ch. Calyx none. Corolla in ſix deep, equal, ſpreading, beardleſs ſegments, deciduous. Filaments inſerted into the baſe of each ſegment, thread-ſhaped, ſmooth, curved at the point; anthers arrow-ſhaped, cohering, longer than the filaments. Style thread-ſhaped, with three furrows; ſtigma ſimple. Berry with a few, nearly globoſe, ſeeds.

This genus conſiſts of climbing weak ſhrubs, with ſimple ribbed leaves. Flowers cymoſe or umbellate, terminal and axillary; their footſtalks as it were articulated with the rather tapering baſe of the flower. Berry black, ſometimes encloſing only a ſingle ſeed. Mr. Brown is not quite certain of his genus being preciſely the ſame with that of the Flora Peruviana. He defines two New Holland ſpecies.

1. L. *cymoſa*. Cymes terminal, deeply divided. Branches round. Young branches ſtriated, ſmooth. Found near Port Jackſon, as well as within the tropic.

2. L. *montana*. Umbels axillary, ſtalked. Branches ſtriated, rough. Found near Port Jackſon.

LUZY, in *Geography*, a town of France, in the department of the Nièvre, and chief place of a canton, in the diſtrict of Chateau-Chinon; 5 leagues S.S.E. of Moulins-en-Gilbert. The place contains 1607, and the canton 8748 inhabitants, on a territory of 417½ kiliometres, in 9 communes.

LUZZANA, a town of Italy; 22 miles S. of Mantua.

LUZZI, a town of Naples, in Calabria Citra; 4 miles S. of Biſignano.

LUZZO Marino, in *Ichthyology*, a name given by the Italians to the fiſh called by the ancient Greek writers, and many of the modern Latin authors, *ſphyræna*; and by Pliny, Varro, and ſome other of the old Roman authors, *ſudis*. Gaza has called it the *malleolus*, and the French, at this time, call it *ſpet*. Salvian has given the figure of it, but it is an imperfect one; for he has omitted the firſt fin of the back.

LYBIA, in *Ancient Geography*. See Libya.

LYCÆA, Λυκαια, in *Antiquity*, an Arcadian feſtival reſembling the Roman *lupercalia*, in which the conqueror was rewarded with a ſuit of brazen armour.

LYCANTHROPIA, in *Ancient Medicine*, from λυκος, *a wolf*, and ανθρωπος, *man*, as it were *man-wolf*, a term applied to that variety of inſanity or melancholy, which induced the perſons affected to wander out in the night, howling and making other noiſes, frequenting church-yards, or places of burial; in which circumſtances they were ſuppoſed to imitate or to reſemble wolves. Aëtius and Paul of Ægina have deſcribed ſuch patients as pale, with dry and hollow eyes, parched tongue and mouth, exceſſive thirſt, and perpetual ſores on their legs, in conſequence of the frequent accidents which they met with. The ſame term was alſo applied to thoſe maniacs, who fancied themſelves transformed into wolves. The appellation of *cynanthropia* was alſo given to the diſeaſe, when the patients imitated the manners of *dogs*, or imagined themſelves to be changed into theſe animals.

LYCAON, in *Zoology*. See *Black* Fox.

LYCAONIA, in *Ancient Geography*, a province of Aſia Minor, ſouth of Galatia. According to Strabo, Iſauria made a part of it. It was ſituated between mountains, and is ſuppoſed to have derived its name from λυκος, *a wolf*, becauſe the country, from its ſituation, formed a proper retreat for thoſe animals. The principal places of Lycaonia, according to Ptolemy, were Adopiſſus Canna, Iconium, Paralais Corna, Caſbia, and Baratta. The apoſtles of this country are ſaid to have been St. Paul and St. Barnabas. The notitia of Hierocles reckons in this province 18 epiſcopal towns.

LYCEUM, Λυκειον, in *Antiquity*, the name of a celebrated ſchool, or academy at Athens, where Ariſtotle explained his philoſophy.

The place was a grove in the ſuburbs of Athens, which had previouſly been uſed for military exerciſes. It was compoſed of porticoes, and trees planted in the quincunx form, where the philoſophers diſputed walking. Hence *philoſophy of the Lyceum* is uſed to ſignify the philoſophy of Ariſtotle, or the Peripatetic philoſophy. Suidas obſerves, that the Lyceum took its name from its having been originally a temple of Apollo Lyceus; or rather, a portico or gallery built by Lyceus, ſon of Apollo: but others mention it to have been built by Piſiſtratus, or Pericles. Here he delivered his lectures to a promiſcuous auditory in the evening, when the Lyceum was open to all young men without diſtinction; but in the morning his diſciples were more ſelect, and ſuch as had been previouſly inſtructed in the elements of learning, and diſcovered abilities and diſpoſitions ſuited to the ſtudy of philoſophy. The latter he called his morning walk, and the former his evening walk. Ariſtotle continued his ſchool in the Lyceum twelve years.

LYCHNANTHUS, in *Botany*, a name given by Gmelin to the *Cucubalus baccifer* of Linnæus, which is ſuperfluous, this plant being perhaps the only true *Cucubalus*; ſee that article.

LYCHNIDEA. See PHLOX and SELAGO.

LYCHNIS, λυχνις; of the Greeks, which word alſo ſignifies a lamp. Hence ſome have ſuppoſed that its botanical application aroſe from the down of the plant having been uſed to make wicks for lamps. This, however, by no means appears to have been the fact. The moſt probable and apparent explanation of the name is from the reſemblance of the calyx to a lanthorn, its ſides being ſemi-tranſparent between the ribs or veins, or the whole, in ſome inſtances, quite membranous, round, and inflated, like the horn lanthorns ſtill uſed by the Chineſe. Poſſibly the appearance of the ſtigmas, ſtamens, or crown of the corolla, in ſeveral ſpecies, might favour the idea of a lamp with its flame. We muſt recollect that this name of *Lychnis* has been always uſed, with great latitude, for all the Campion tribe, by the old botaniſts; though now reſtricted, by Linnæus and his followers, to one particular genus of that family. The ſhort mention in Dioſcorides, of his λυχνις, is quite inſufficient to determine either the wild or garden plant of which he ſpeaks. Linn. Gen. 231. Schreb. 312 Willd. Sp. Pl. v. 2. 807. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 493. Ait. Hort. Kew. ed. 2. v. 3. 132. Juſſ. 302. Lamarck Illuſtr. t. 391. Gærtn. t. 130.—Claſs and order, *Decandria Pentagynia*. Nat. Ord. *Caryophyllei*, Linn. Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, oblong, tubular, membranous, five-toothed, permanent. *Cor.* Petals five; their claws the length of the calyx, flat, each crowned with a double erect ſcale; border flat, wedge-ſhaped, often divided. *Stam.* Filaments ten, longer than the calyx, fixed to the claws of the petals, five alternate ones later than the reſt; anthers incumbent. *Piſt.* Germen ſuperior, nearly ovate; ſtyles five, awl-ſhaped, longer than the ſtamens; ſtigmas downy, reflexed contrary to the motion of the ſun. *Peric.* Capſule more or leſs ovate, clothed with the calyx, of from one to five cells, opening by five rigid reflexed teeth at the top. *Seeds* numerous, roughiſh, ſomewhat kidney-ſhaped.

Obſ. L. *dioica* has the ſtamens and piſtils in ſeparate flowers and on different plants. *L. Viſcaria* has undivided petals, and a capſule of five cells. Some other ſpecies are eſteemed to vary in the number of their ſtyles from five to four, or even three. *L. apetala* has the corolla concealed within the calyx.

Eſſ. Ch. Calyx of one leaf, oblong. Petals five, with claws; the border uſually divided. Capſule ſuperior, with five teeth at its orifice, of from one to five cells.

Ten ſpecies of *Lychnis* occur in the fourteenth edition of *Syſt. Veg.*, of which one, *alpeſtris* of the *Supplementum*, is made by Jacquin, Aiton, and Willdenow, a *Silene*, ſurely with great propriety. But there can be no doubt that *quadridentata* ought to be referred to the ſame genus, as having naturally only three ſtyles, or at moſt but four. Theſe two ſpecies being removed hence, the above-mentioned anomaly in the number of the ſtyles in the preſent genus is done away; for *alpina*, reputed to have four ſtyles, is now known to have naturally, if not invariably, five; ſee Engl. Bot. t. 2254. We therefore retain but eight of the ſpecies of Linnæus, or rather of Murray, for Linnæus was originally correct reſpecting the above. To theſe eight two are added by Willdenow, from Aiton and Lamarck.

1. L. *chalcedonica.* Scarlet Lychnis. Linn. Sp. Pl. 625. Curt. Mag. t. 257. Ger. em. 466.—Tufts terminal, level-topped, many-flowered. Leaves ovate, rough, ſomewhat undulated.—This is ſaid by Gmelin to grow wild in all parts of Ruſſia and Siberia. It is one of the oldeſt ornaments of our flower-gardens, being a hardy perennial, very ſhowy, and remarkable for the rich deep ſcarlet of its bloſſoms, eſpecially when double. Theſe appear in June and July, forming a large, denſe, convex, terminal tuft, two or three inches wide. The *ſtem* is three or four feet high, round, hairy, leafy, but little branched. *Leaves* ſeſſile, oppoſite, pointed, wavy, rough, dark green, claſping the ſtem with their broad, ovate, often combined, baſes. We have never ſeen the pale red, nor the white varieties, mentioned by authors.

2. L. *Flos cuculi.* Meadow Lychnis, or Ragged Robin. Linn. Sp. Pl. 625. Curt. Lond. faſc. 1. t. 33. Engl. Bot. t. 573. (Armoraria pratenſis; Ger. em. 600.)—Petals in four deep, linear ſegments. Leaves lanceolate, ſmooth. Fruit roundiſh, of one cell.—Frequent in moiſt meadows throughout Europe, flowering in June. The *root* is perennial. *Stem* twelve or eighteen inches high, with rough angles, viſcid above. *Leaves* narrow. *Panicle* forked. *Petals* pink, very delicate, with a brown, angular, ſmooth calyx. There is a double variety, and ſome mention a white one.

3. L. *Viſcaria.* Red German Catchfly. Linn. Sp. Pl. 625. Fl. Dan. t. 1032. Engl. Bot. t. 788. (Muſcipula anguſtifolia; Ger. em. 601.)—Petals undivided. Leaves linear-lanceolate, ſmooth. Fruit of five cells.—Native of dry or rocky paſtures in the north of Europe. We have gathered it in the fiſſures of rocks, a mile ſouth of Edinburgh, and have it alſo from Perthſhire. It flowers in May and June. A double variety is common in gardens, and a pure white one is ſometimes ſeen. The *roots* are woody, tufted, and perennial. *Herb* ſmooth. *Stem* a foot high, angular, brown and very clammy under each joint. *Leaves* narrow. *Flowers* in a denſe, forked, oblong bunch or ſpike. *Petals* crimſon, only ſlightly emarginate, not cut or cloven. *Capſule* ovate, of five cells, though this ſpecies is ſo nearly allied in habit to the foregoing, whoſe capſule has but one cell.

4. L. *alpina.* Red Alpine Campion. Linn. Sp. Pl. 626. Tour in Lapland, v. 2. 19. Curt. Mag. t. 394. Fl. Dan t. 65. Engl. Bot. t. 2254.—Smooth. Petals cloven. Flowers corymboſe. Leaves linear-lanceolate.—Native of the Lapland, Siberian, Swiſs and Pyrenean mountains; diſcovered on the Clova mountains of Anguſhire, by Mr. G. Don, in 1795. It is much ſmaller than the laſt, and not at all viſcid. The *petals* are divided at leaſt half way down, and their crown is but ſmall. See Sm. Tr. of Linn. Soc. v. 10. 342, for the confuſion and contrariety of deſcription which has attended this ſpecies.

5. L. *magellanica.* Magellanic Campion. Lamarck Dict. v. 3. 641. Willd. n. 7.—Somewhat hairy. Leaves linear. Petals cloven, ſcarcely longer than the calyx.—Fruit of one cell.—Gathered by Commerſon in the Straits of Magellan. We know this ſpecies ſolely by Lamarck's account. He compares its habit and foliage to that of Thrift, *Statice Armeria*, but obſerves that it is next akin to L. *alpina*, differing in having narrower, and ſomewhat downy *leaves*, fewer and

larger *flowers*, whoſe petals ſcarcely exceed the length of their bell-ſhaped calyx.

6. L. *ſibirica*. Siberian Campion. Linn. Sp. Pl. 626. —Hairy. Leaves lanceolate. Stem forked, many-flowered. Petals cloven, twice as long as the calyx. Fruit of one cell. —Gathered in Siberia by Gmelin, who ſent it to Linnæus, but it does not find a place in the *Flora Sibirica*. This has greatly the habit of *Silene alpeſtris* above-mentioned, but is all over hairy; the *petals* more obtuſe, and leſs deeply cloven; the *ſtyles* five. The *root* is very long and ſimple, tufted at the crown, bearing numerous *ſtems* a ſpan high, which are about twice forked. *Calyx* bell-ſhaped, tapering at the baſe. *Petals* apparently reddiſh. *Capſule* ovate, of one cell, with recurved irregular teeth.

7. L. *læta*. Small Portugal Campion. Ait. Hort. Kew. ed. 1. v. 2. 118.—"Petals cloven. Flowers ſolitary. Leaves linear-lanceolate, ſmooth. Calyx with ten ribs."—Brought from Portugal, by the late Dr. Edward Whittaker Gray, in 1778, to Kew garden, where it is ſaid to be a hardy annual, flowering in July. If this ſpecies ſtill exiſts, it ought to be figured in ſome periodical work; it being greatly to be wiſhed that the authors of ſuch would prefer unpubliſhed plants to thoſe already often delineated. We know of no plate of this or the laſt-mentioned.

8. L. *coronata*. Chineſe Lychnis. Thunb. Jap 187. Linn. Syſt. Veg. ed. 14. 435. Curt. Mag t. 223. (L. grandiflora; Jacq. Col. v. 1. 149. Ic. Rar. t. 84. Hedona ſinenſis; Lour. Cochinch. 286; ſee HEDONA.)—Leaves elliptic-lanceolate, ſmooth. Flowers axillary or terminal, ſolitary. Petals jagged.—Native of China and Japan, from whence Dr. Fothergill procured the plant in 1774. It flowers in June or July, or later, and muſt be kept in the greenhouſe in winter, or at leaſt protected by extraordinary covering, if left in the border. The *root* is perennial. *Stem* weak, round, ſmooth, two feet high. *Leaves* elliptic-lanceolate, pointed, ſmooth, pale beneath. *Flowers* remarkable for their great ſize, ſharply jagged petals, and red-lead, very vivid, colour.

9. L. *dioica*. Red or White Field Campion. Linn. Sp. Pl. 626.—α (red) Curt. Lond. faſc. 2. t. 32. Engl Bot. t. 1579.—β (white) Fl. Dan. t. 792. Engl. Bot. t. 1580. Leaves hairy. Flowers dioecious. Fruit of one cell. Crown of each petal four-cleft.—A very common plant throughout Europe; the red-flowered kind in hedges and ſhady buſhy places in ſpring; the white more uſually in fields or open ſituations in ſummer. The latter is a ſtronger plant, and from its evening fragrance has been called L. *veſpertina* by Dr. Sibthorp, while the former is his *diurna*; ſee Fl. Oxon. 145, 146. Both are uſually dioecious, but not invariably ſo. There is a bluſh-coloured variety, otherwiſe moſt like the white; but we have found it in cultivation ſoon evaneſcent. The *roots* of both are perennial. *Plant* hairy and ſomewhat viſcid, two or three feet high. *Stem* forked. *Leaves* ovate or lanceolate. *Limb* of each petal cloven half way down, generally with two ſmall acute lateral lobes, its crown moreover conſiſting of two obtuſe central teeth, and two acute lateral ones.

10. L. *apetala*. Apetalous Mountain Campion. Linn. Sp. Pl. 626. Fl. Lapp. ed. 2. 150. t. 12. f. 1.—Calyx inflated, longer than the petals. Stem nearly ſingle-flowered. —Native of the mountains of Lapland and Siberia. The *root* is perennial. *Stem*, in the Lapland ſpecimens, a ſpan high, and quite ſimple, ſingle-flowered; in ſome of Gmelin's, from Siberia, taller, with from three to five flowers. The whole *herb* is ſlightly downy. *Leaves* lanceolate, rather narrow. *Flower* drooping. *Calyx* ovate, cloſed, with ten rough, purpliſh-brown ribs. *Petals* ſmall and narrow, with an obſolete browniſh border, entirely included, along with the ſtamens and piſtil, in the hollow of the calyx. *Capſule* obtuſe, of one cell.

LYCHNIS, in *Gardening*, contains plants of the hardy, herbaceous, flowery, perennial kind, of which the ſpecies cultivated are the ſcarlet lychnis (L. chalcedonica); the red-flowered lychnis, meadow pink, or ragged robbin, (L. flos cuculi); the Chineſe lychnis (L. coronata); the viſcous lychnis, or catchfly, (L. viſcaria); the roſe-flowered lychnis, wild red campion, or red bachelor's buttons (L. diurna); and the white-flowered lychnis, wild white campion, or white bachelor's buttons, (L. veſpertina.)

In the firſt ſort there is a variety with very double flowers, of a beautiful ſcarlet colour, they are produced in cloſe cluſters, ſitting upon the top of the ſtalk; when the roots are ſtrong, the cluſters of flowers are very large, and make a fine appearance, coming out the latter end of June, and in moderate ſeaſons continue nearly a month in beauty.

Of the fifth ſort there is a variety with double flowers, cultivated in gardens by the name of red bachelor's buttons, which is an ornamental plant, and continues long in flower.

And the ſixth ſort has varieties with purple, or bluſh-coloured flowers; with quadrifid petals; with hermaphrodite flowers; with double flowers, cultivated in gardens by the name of double white bachelor's buttons.

Method of Culture.—They may be increaſed with facility in the ſingle ſorts by ſeed, and parting the roots; and in the double ones by dividing or ſlipping the roots; and ſometimes by cuttings of their ſtalks.

The ſeed ſhould be ſown in the early ſpring, as in March, in a bed or border of light earth, in an eaſtern aſpect, each ſort ſeparate, raking them in lightly, or they may be ſown in ſmall drills. The plants come up in two or three weeks, when they ſhould have occaſional waterings and hand-weedings: and when the plants are two or three inches high, be planted out in beds or borders, in rows ſix inches aſunder, watering them till freſh-rooted, letting them remain till the autumn or following ſpring, when they ſhould be tranſplanted where they are to remain.

Both the ſingle and double may be increaſed by ſlipping the roots, but it is more particularly applicable to the double ſort, as they cannot with certainty be obtained from ſeed: the ſeaſon for performing this work is the autumn after the ſtalks decay, when the whole root may either be taken up and divided into as many ſlips as are furniſhed with proper root-fibres, or the main root ſtand, and as many of the outer offsets as ſeem convenient to be ſlipped off: theſe ſlips, when ſtrong, ſhould be planted at once where they are to remain; but when rather ſmall and weak, it is better to plant them in nurſery rows, half a foot aſunder, to remain a year, and then tranſplant them for good where they are to ſtand.

The planting of cuttings of the ſtalks is moſtly practiſed for the double ſcarlet ſort, when it increaſes but ſparingly by offsets of the root. It is performed in ſummer, when the ſtalks are well advanced in growth, but before they flower, or have become hard and woody. Some of them ſhould be cut off cloſe to the bottom, and divided into lengths of four or five joints, planting them in an eaſterly border of rich, moiſt loamy earth, two thirds of their length into the ground, leaving only one joint or eye out, watering them directly, and repeating it occaſionally with neceſſary ſhade in hot weather. They will be well rooted, and form proper plants for tranſplanting in the autumn. If the cuttings, as ſoon as planted, are covered down cloſe with hand-glaſſes, it will greatly promote their rooting, ſo as to form ſtronger plants before the winter ſeaſon comes on.

The only culture they require afterwards is clearing them from weeds in ſummer, and ſupporting with ſtakes thoſe which need it, cutting down and clearing away the decayed ſtalks in the autumn.

Of the third ſort, as being rather more tender, ſome plants ſhould be planted in pots, for moving under the protection of a frame or greenhouſe in the winter ſeaſon.

All theſe plants are very ornamental for the pleaſure-ground, particularly the doubles, and proſper in any common ſoil, remaining in all weathers unhurt, being of many years duration in root; and, when of ſome ſtanding, ſend up many ſtalks every ſpring, terminated by numerous flowers, making a fine appearance in ſummer. The ſcarlet double lychnis claims the preference, though the ſingle ſcarlet ſort is alſo very ſhowy. And all the other ſpecies in their reſpective double-flowered ſtates are ornamental. They are all kept in the nurſeries for ſale. In planting out, the talleſt growers ſhould be placed the moſt backward, and the others more towards the front.

LYCHNITIS MARMOR. See MARBLE.

LYCIA, in *Ancient Geography*, a country of Aſia Minor, originally called Mylias, from the Mylliæ, a people of Crete, who ſettled there, and afterwards Lycia, from Lycus, the ſon of Pandion, king of Athens; ſituated upon the Mediterranean, and forming a kind of peninſula, on the weſt of which was the Glaucus Sinus, and on the eaſt another gulf, in the lower part of which was Attalea. To the ſouth was the Mediterranean. The adjacent countries were on the weſt, Caria, to the north a ſmall part of Phrygia Pacatiana, and to the north-eaſt Pamphylia. Its boundaries were various at different times. Ptolemy places in Lycia the countries called Mylias and Carbalia, or Cabalia. Pliny ſays that the Lycians had thirty-ſix towns; Strabo aſcribes to them twenty-three, of which ſix were very conſiderable. Lycia was interſected by ſeveral chains of mountains, paſſing from the north and north-eaſt, and extending towards the ſea. The moſt conſiderable rivers were the Xanthus and Limyrus. Its principal towns were Telmiſſus, Pinara, Xanthus, Patara, Myra, Limyra, Olympus, and Phaſelis. The ſix towns, particularly noticed by Strabo, after Artemidorus, were Xanthus, Patara, Pinara, Olympus, Myra, and Tlos. The chief mountains of Lycia were Taurus and Chimæra. In the firſt ages of Chriſtianity, Hierocles reckons as epiſcopal thirty towns, and Leon le Sage thirty-eight. The inhabitants of Lycia were originally from the iſland of Crete: and they were for a long time addicted to piracy. Diodorus Siculus, and Plato before him, reckon the Lycians among the Greek nations of Aſia, as being deſcended from the Argians. Although they were governed by kings, it does not appear that the government was completely monarchical; a confederacy having been formed by twenty-three cities, which ſent deputies to a general aſſembly, by which the affairs of the nation were managed. The ſoil of this country was fruitful, and the air reckoned very wholeſome. The Lycians are highly commended by the ancients for their ſobriety, and manner of adminiſtering juſtice. They continued to be governed by their own kings after they were ſubdued by the Perſians, paying them tribute. They afterwards fell with the Perſians under the power of the Macedonians, and after the death of Alexander, were governed by the Seleucidæ. When Antiochus the Great was confined by the Romans beyond mount Taurus, Lycia was granted to the Rhodians; but theſe diſobliging the Romans in the war with Perſeus, Lycia was declared a free country, and continued in this ſtate till the reign of Claudius, who, provoked at their inteſtine diſſentions, reduced their country into the form of a province.

LYCIUM, in *Botany*, λυκιον, of the Greeks, ſo called, as is generally ſuppoſed, from Lycia, its native country; but what was the preciſe plant intended, has never been ſettled by commentators. Dioſcorides deſcribes it as a "ſpinous tree, with twigs three cubits or more in length, bearing thick-ſet leaves, like box. The fruit is like pepper, black, thick-ſet, bitter, and ſmooth. Bark pale. Roots woody." This deſcription accords in many points with ſome ſpecies of the received *Lycium*, but with none, that we are acquainted with, in every point. Box-thorn. Linn. Gen. 103. Schreb. 136. Willd. Sp. Pl. v. 1. 1057. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2, 3. Sm. Prodr. Fl. Græc. Sibth. v. 1. 155. Juſſ. 126. Lamarck Illuſtr. t. 112. Gærtn. t. 132. (Jaſminoides; Mich. Gen. 224. t. 105. Duhamel Arb. v. 1. 305.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, ſmall, ſlightly five-cleft, obtuſe, erect, permanent. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, ſpreading, incurved; limb ſmall, in five deep, obtuſe, ſpreading ſegments. *Stam.* Filaments five, awl-ſhaped, inſerted into the middle of the tube, and cloſing its orifice with their beard-like hairineſs, ſhorter than the limb; anthers erect. *Piſt.* Germen ſuperior, roundiſh; ſtyle ſimple, projecting beyond the ſtamens; ſtigma cloven, thickiſh. *Peric.* Berry roundiſh, of two cells. *Seeds* ſeveral, kidney-ſhaped. *Receptacles* convex, fixed on each ſide of the partition.

Eſſ. Ch. Corolla tubular; its orifice cloſed by the beards of the filaments. Berry of two cells, with many ſeeds.

The ſpecies of this genus have been very imperfectly explained in many of the works of Linnæus. The fourteenth edition of *Syſt. Veg.*, edited by Murray, contains eleven, of which the firſt and fifth are one and the ſame plant, no *Lycium* at all, but the *Seriſſa* of Juſſieu; ſee Willd. Sp. Pl. v. 1. 1061; ſee alſo our article DYSODA. The ſeventh and eighth alſo are but one ſpecies, *boerhaavifolium* of Linn. Suppl. and the eleventh, *capſulare* of Sp. Pl. 278, appears, by the Linnæan herbarium, to be a nondeſcript ſpecies of *Hydrolea*; called *glabra* in the Bankſian collection, where is the other half of the very ſame ſpecimen, of which a part was ſent to Linnæus by Miller, who received it from New Spain. Seven, therefore, only of the above number remain, to which three are added from Thunberg, in Willdenow. The latter, therefore, is correct in his enumeration, except with reſpect to the *capſulare*. But Thunberg has given more recent illuſtration of his own new ſpecies in the ninth volume of the Linnæan Society's Tranſactions, with plates. We ſhall briefly deſcribe the whole, with an additional ſpecies from Michaux.

1. L. *afrum*. African Box-thorn. Linn. Sp. Pl. 277. (L. foliis linearibus; Trew. Ehret. 4. t. 24. Jaſminoides aculeatum humile, halimi minoris folio, flore majori violaceo, fructu craſſiore, per maturitatem flaveſcente; Mich. Gen. 224. t. 105. f. 2.)—Leaves cluſtered, linear, tapering at the baſe. Branches ſtraight, ending in a ſpine.—Native of the north of Africa, and ſome parts of Spain. It has been long cultivated in the greenhouſes of the curious, but has little to attract general admiration. The *ſtem* is ſhrubby, rigid, much branched; each branch ending in a ſtiff ſtraight ſpine. *Leaves* linear, bluntiſh, entire, various in length and breadth, many together in lateral cluſters, ſmooth, rather glaucous and fleſhy. *Flowers* ſolitary, purple, about an inch long, drooping; on ſimple ſtalks, uſually twice or thrice as long as the calyx. Linnæus cites Micheli very

erroneouſly, which Willdenow, not turning to the book, has omitted to correct.

2. L. *rigidum.* Rigid Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 153. t. 14.—Leaves cluſtered, linear. Branches ſtraight, ending in a ſpine. Flowers nearly ſeſſile.—Gathered by Thunberg near Cape Town, flowering in July and Auguſt. It differs from the former chiefly in having the *flowers* nearly ſeſſile, with a much ſhorter and broader *corolla.* The *leaves* alſo are narrower.

3. L. *ruthenicum.* Tartarian Box-thorn. Murr. Comm. Gott. for 1779, p. 2. t. 2. Ehrh. Exſicc. n. 4. (L. tataricum; Pall. Roſſ. v. 1. faſc. 1. 78. t. 49.)—Leaves linear, cluſtered, from ſpinous buds. Branches elongated, pendulous.—Native of Siberia and Tartary. The *branches* are long, ſlender, pendulous, compound, with a pale ſmooth bark, and a ſolitary prominent ſpine from each bud. *Leaves* linear, bluntiſh, tapering at the baſe, ſcarcely more than three or four in each cluſter. *Flowers* drooping. *Corolla* funnel-ſhaped, about half an inch long, pale purple. *Calyx* ſomewhat two-lipped. This is ſmaller in all its parts than the following.

4. L. *barbarum.* Willow-leaved Box-thorn, or Blue Jaſmine. Linn. Sp. Pl. 277. Schkuhr. Handb. v. 1. 147. t. 46.—Leaves lanceolate, ſolitary or cluſtered, very unequal. Spines axillary. Branches elongated, pendulous.—Native of Europe, Aſia, and Africa, very hardy with us, and long cultivated for bowers and trelliſes, being a rambling ſhrub of very luxuriant growth, though no great beauty. Its *flowers* are purple. *Berries* of an orange-red. The Chineſe variety, diſtinguiſhed by gardeners, and figured by Duhamel, differs ſcarcely in any thing. The *calyx* is occaſionally three or five-cleft, and ſomewhat two-lipped, in that as well as the ordinary kind. This plant bloſſoms from May to the very end of autumn, bearing flowers and fruit together in abundance.

5. L. *tetrandrum.* Four-cleft Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 154. t. 15. Linn. Suppl. 150.—Leaves obovate, cluſtered. Branches ſtraight, angular, ending in a ſpine. Flowers four-cleft.—Native of the Cape of Good Hope, towards the ſea, flowering in June. *Thunb.* A rigid, branched, ſmooth *ſhrub,* with the habit of the firſt two ſpecies, but very ſmall, fleſhy, obovate *leaves,* and ſmall, funnel-ſhaped, ſhort, white *flowers,* whoſe *corolla* is four-cleft, and *ſtamens* four only.

6. L. *cinereum.* Grey-barked Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 154. t. 16.—Leaves lanceolate, cluſtered, nearly equal. Branches ending in a ſpine. Flowers on very ſhort ſtalks.—Found at the Cape of Good Hope by Thunberg. He deſcribes the *ſtem* as round, ſtriated, ſmooth, grey, much branched, zigzag, and erect; the *branches* alternate, ſlender, elongated, each terminating in a ſharp ſpine. *Leaves* ſmooth, acute. *Flowers* axillary, ſolitary, on ſtalks ſcarcely longer than the calyx, and not half the length of any of the leaves.

7. L. *horridum.* Succulent-leaved Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 154. t. 17.—Leaves obovate, fleſhy, ſmooth. Branches numerous, ending in a ſpine. Flowers on very ſhort ſtalks.—Grows in maritime ſituations at the Cape, flowering from September to November. *Thunb.* The *ſtem* is three feet high, rigid, abounding with ſhort ſpinous *branches* in every direction. *Leaves* from three to ſeven in a cluſter, not half an inch long, ſeſſile, thick, ſmooth; flattiſh and green above; convex, white, and marked with a green line, beneath. *Flowers* ſolitary, ſmall, on ſhort ſtalks. They are repreſented in the figure with four ſegments only, though of this nothing is ſaid in the character or deſcription. If it be correct, the preſent ſpecies comes very near the fifth.

8. L. *europæum.* European Box-thorn. Linn. Sp. Pl. ed. 1. 192. Mant. 47. (Jaſminoides aculeatum, ſalicis folio, flore parvo, ex albo purpuraſcente; Mich. Gen. 224. t. 105. f. 1.)—Leaves obovate, oblique, cluſtered. Spines lateral and terminal. Stem erect.—Native of the ſouth of Europe; hardy in our gardens, flowering all ſummer long. Linnæus confounded this, in the ſecond edition of *Sp. Pl.*, with his *barbarum,* from which it is very diſtinct. The *ſtem* and *branches* are firm and upright. *Leaves* obovate, oblique or twiſted, ſometimes minutely downy. Corolla paler, longer, and more ſlender. There is no prominent green line, running down the branches from each bud, as in the *barbarum.*—The preſent is *Rhamnus primus* of Cluſius and Dodonæus; ſee Ger. em. 1334. fig. 1.

9. L. *boerhaavifolium.* Glaucous-leaved Box-thorn. Linn. Suppl. 150. (L. heterophyllum; Murr. Comm. Gott. for 1783. p. 6. t. 2. Ehretia halimifolia; l'Herit. Stirp. faſc. 1. 45. t. 23.)—Leaves ovate, oblique, acute, glaucous. Spines lateral. Flowers in terminal cluſters.—Native of Peru. This is a very pretty *ſhrub,* with ſpines accompanying the buds on the ſtem and older branches; the young ſhoots are unarmed, ſlender, ſpreading horizontally. *Leaves* ſcattered, ſtalked, about an inch long, ovate, entire, glaucous, ſmooth. *Flowers* ſeveral together, in a cluſter, or ſhort panicle, at the end of each branch, purpliſh, very fragrant. *Calyx* hemiſpherical, with five ſharp equal teeth. *Corolla* rather ſhort and funnel-ſhaped, with long projecting ſtamens and ſtyle; the former hairy at the baſe. The *ſtigma,* according to l'Heritier, is ſometimes capitate, ſometimes cloven, or of two valves, which muſt ſurely be owing to the different periods of its age.

10. L. *barbatum.* Fringed Box-thorn. Murr. in Syſt. Veg. ed. 14. 228. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 155. (L. inerme; Linn. Suppl. 150.)—Leaves ovate, ſmooth. Branches zigzag, without ſpines. Panicles axillary.—Gathered by Thunberg at the Cape of Good Hope, on little hills about Cape-town and elſewhere, flowering in Auguſt and the following months. "The *ſtem* is ſhrubby, quite ſmooth, two feet high or more, with alternate, ſpreading, zigzag, rugged, grey *branches.* *Leaves* oppoſite, ſtalked, ovate, pointed or bluntiſh, entire, ſmooth, green above, pale beneath, an inch or more in length. *Footſtalks* three quarters of an inch long. *Flowers* axillary, panicled, on capillary ſtalks. *Stipulas* or *bracteas* fringed with white. *Berry* two-lobed, compreſſed, abrupt, with two furrows and two cells." *Thunb.*—Of this we have neither ſeen a ſpecimen nor figure, nor has it yet appeared in any Engliſh garden.

11. L. *carolinianum.* Carolina Box-thorn. Mich. Boreal-Amer. v. 1. 95. Donn Cant. ed. 5. 47.—Leaves ſpatulate-oblong. Branches without ſpines. Flowers four-cleft.—Native of the ruſhy ſalt-marſhes of Carolina, Georgia, and Florida. Said to have been brought to England in 1806. The *ſtem* is ſhrubby. *Leaves* narrow. *Flowers* blueiſh, four-cleft, with four ſtamens.

LYCIUM, in *Gardening,* contains plants of the ſhrubby exotic kind, of which the ſpecies cultivated are the African boxthorn (L. afrum); the willow-leaved boxthorn (L. barbarum); the European boxthorn (L. europæum); and the Tartarian boxthorn (L. tartaricum).

The ſecond ſort affords ſeveral varieties. The firſt has a ſhrubby ſtalk ſeven or eight feet high, ſending out ſeveral irregular branches, armed with ſtrong ſpines, and furniſhed with ſhort thick leaves: the flowers which come out from the ſide of the branches are ſmall and purple. They appear in July and Auguſt, but do not produce ſeeds in this climate.

The ſecond has the ſtalk four or five feet high, ſending out many irregular branches, covered with a very white bark, and armed with a few ſhort ſpines; the leaves are about three inches long, and one inch broad in the middle, alternate, pale green. The flowers appear in May, and are ſucceeded by ſmall round berries that ripen in the autumn, when they become as red as coral.

The third riſes with weak irregular diffuſed branches to a great height, requiring ſupport; ſome of theſe branches have in one year been upwards of twelve feet long; the lower leaves are more than four inches long, and three broad in the middle; they are of a light green and a thin conſiſtence, placed without order on every ſide of the branches. As the ſhoots advance in length, the leaves diminiſh in ſize, and towards the upper part are not more than an inch long and a quarter of an inch broad; ſitting cloſe to the ſtalks on every ſide. The flowers come out ſingly at every joint towards the upper part of the branches, on ſhort tender peduncles, and are of a pale colour with ſhort tubes; the brims are ſpread open, broader than either of the former ſorts, and the ſtyle is conſiderably longer than the tube of the corolla.

Method of Culture.—All theſe plants may be increaſed by ſeeds, cuttings, or layers.

The ſeeds ſhould be ſown in the autumn ſoon after they are ripe, in pots, being plunged into an old tan-bed in winter, and covered with the glaſſes in froſty weather; but in mild weather be open to receive moiſture; in the following ſpring the pots ſhould be plunged into a moderate hot-bed, to bring up the plants, which muſt be inured to bear the open air as ſoon as the danger of froſt is over, and when they are three inches high, be ſhaken out of the pots, and each planted in a ſmall ſeparate pot filled with loamy earth, being placed in the ſhade till they have taken new root, when they may be removed to a ſheltered ſituation, to remain till the autumn, when they ſhould be either removed into the greenhouſe, or placed under a hot-bed frame, to ſhelter them from hard froſt. They muſt at firſt be kept in pots, and treated in the ſame way as myrtles, and other hardy greenhouſe plants; but when they are grown ſtrong, a few of them may be planted out in the open ground in warm ſituations, where they ſtand moderate winters, but are commonly deſtroyed by hard froſts.

The cuttings ſhould be made from the young ſhoots, and be planted in a ſhady border in July, being duly watered; and when they have taken root, be treated in the ſame manner as the ſeedling plants. This is the uſual mode of increaſing them, as ſome ſorts never produce ſeeds in this climate.

In the third ſort the cuttings ſhould be planted in the ſpring, in an eaſtern border; and the plants ſhould not be removed till the autumn, when they may be planted to cover walls, as the branches are too weak to ſupport themſelves.

The third variety may alſo be increaſed by dividing and planting its creeping roots.

The layers muſt be made from the young branches, and be laid down in the ſpring; and when rooted in the autumn, taken off, and managed as in the other methods.

The hardy ſorts afford variety in warm ſituations in the open ground, and the other ſorts among greenhouſe collections.

Lycium, in the *Materia Medica*, the name of a fruit called by the French *baye d'Avignon*, the Avignon berry, and by many authors the *pyracantha*. The ſhrub which produces it is the lycium ſive pyracantha of Gerrard. (See Lycium, *ſupra*) The fruit is about the ſize of a grain of wheat, and is not round, but of an angular form when dried, ſometimes of three, ſometimes of four angles, and ſometimes dented in at one end like a heart. It is of a yellowiſh-green colour, and of a bitter and aſtringent taſte. It ſhould be choſen freſh dried, and large. There was formerly a rob, or inſpiſſated juice made from theſe berries, much in uſe in medicine; but this was generally adulterated with a rob made of the berries of the woodbine, privet, ſloe, or other ſhrub, and is now quite out of uſe. The dyers in France and Holland uſe it for a yellow; and the Dutch have another uſe for it, which is, that they boil it in alum-water, and mixing it in whiting, form it into twiſted ſticks, which they ſell to the painters in water-colours, under the name of *ſtil de grain*.

LYCOCTONON. See Aconite.

LYCODONTES. See Bufonitæ.

LYCOGALA, in *Botany*, ſo named by Micheli, from λυκος, *a wolf*, and γαλα, *milk*, a genus of the fungus tribe, whoſe internal appearance and ſubſtance, in an early ſtate, are like a maſs of thick cream. It is included under *Mucor* by Linnæus, Schreber, and others. Perſ. Syn. 157. Mich. Gen. 215. t. 95. Albert. and Schwein. 83. (Reticularia; Bulliard Fung. v. 1. t. 476. f. 1—3.)—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eſſ. Ch. Caſe roundiſh, membranous, ſmooth, lodging a maſs, originally pulpy and deliqueſcent, finally powdery intermixed with diſtant internal fibres.

1. L. *argenteum*. (L. griſeum majus; Mich. Gen. 216. t. 95. f. 1. Reticularia Lycoperdon, var. 2; Bull. Fung. v. 1. 95. t. 476. f. 1. Mucor lycogalus; Bolt. Fung. v. 3. 133. t. 133. f. 2)—Cuſhion-ſhaped, ſomewhat hemiſpherical, naked, even of a ſilvery white.—Found upon rotten wood in autumn.—About an inch or more in diameter, brown and pulpy when young, of a brilliant white when arrived at maturity, diſcharging, by one or more irregular accidental openings, a maſs of rich dark ſnuff-coloured powder.

2. L. *turbinatum*. (Reticularia Lycoperdon, var. 3; Bull. v. 1. 95. t. 476. f. 2.)—Top-ſhaped, naked, even, pale brown.—Found in ſimilar ſituations, though rarely. But half the ſize of the former, at moſt, and furniſhed with a kind of ſhort ſtalk, which gives it a pear-ſhaped figure. Hence Perſoon was induced to make this a diſtinct ſpecies, though he appears to have known it merely by the account of Bulliard. The latter ſays it is pellucid when young.

3. L. *punctatum*. (Reticularia Lycoperdon, var. 4; Bull. v. 1. 95. t. 476. f. 3.)—Aggregate, globoſe, dotted, greyiſh.—Found on rotten wood.—Nearly as big as the firſt, but more globoſe, and of an aſhy-grey; its ſurface dotted all over with minute points.

4. L. *atrum*. Albert. and Schwein. n. 233. t. 3. f. 3.—Cuſhion-ſhaped, black. Its powder is intermingled with branched, tree-like, radiating fixed threads. This, not mentioned by Perſoon, is deſcribed by the above authors of the *Conſpectus* of Fungi, growing near Niſke in Upper Luſatia, as found upon fir trees from April to June, and more ſparingly in October and November. It is the ſize and ſhape of the firſt ſpecies; white in the beginning, then of a dirty yellow, afterwards reddiſh-brown, and finally black. This fungus is remarkable for leaving, as it were, a ſkeleton of branched black fibres, radiating from a centre, when the coat and powder are gone.

5. L. *miniatum*. Perſ. n. 4. (L. miniata; Perſ. Obſ. Mycol. faſc. 2. 26. L. globoſum, grani piſi magnitudine, æris recocti colore; Mich. Gen. 216. t. 95. f. 2. Lycoperdon

don epidendrum; Linn. Sp. Pl. 1654. Hudſ. 645. With. v. 4. 385. Sowerb. Fung. t. 52. Bolt. Fung. v. 3. 119. t. 119. f. 1. Mucor; Schæff. Fung. t. 193.)—Aggregate, globoſe; at firſt ſcarlet; then brown, with roſe-coloured powder.—Common on the trunks of trees, after rain, in ſummer and autumn. Its vivid vermilion or ſcarlet hue, when young, is very ſtriking. In decay it turns brown or black. Mr. Sowerby has exhibited, in his t. 400. f. 2, 3, what he eſteems a luxuriant variety of this, but which ſeems to us a diſtinct ſpecies, being much larger, confluent, pale pink and veiny, ſoon turning quite black. In an early ſtate it looked like the inteſtines of a fowl.—*Lycoperdon piſiforme* of Linnæus is judged by Perſoon to be only a roughiſh-coated variety of this *Lycogala miniatum*.

6. L. *conicum*. Perſ. n. 5.—Scattered, conical; at firſt red; then purpliſh-violet.—Found, very rarely, on the rotten trunks of trees. About one or two lines high, exactly conical, but obtuſe, clothed with little ſcattered fibrous granulations. Powder of a violet red. *Perſoon.*

LYCOIDES, a term uſed by medical writers to expreſs the diſorders which ariſe in the human body by a long retention of the ſeed. Theſe are ſometimes madneſs, and very often dangerous quinſies and ſwellings, and inflammations about the neck and throat. If we conſider the natural tendency of the diſorders of this kind to affect the neck, and the remarkable ſwelling of the necks of bucks, and ſome other animals at rutting time, it may give ſome rational hints towards underſtanding the alteration of the voice in boys who arrive at puberty.

Blancard derives the word *lycoides*, from λυκος, *lupus*, and ειδος, *forma*, from a ſuppoſition that wolves are ſubject to this diſorder.

LYCOMING, in *Geography*, a county of America, in the N.W. part of Pennſylvania, bounded N. by the ſtate of New York, and W. by Alleghany county; 150 miles long and 86 broad, being the largeſt in the ſtate. The north and weſt parts are unſettled. It is divided into 10 townſhips, and contains 5414 inhabitants.—Alſo, a creek, which runs ſouth, and diſcharges itſelf into the W. branch of Suſquehanna, a few miles W. of Loyalſock creek.

LYCOPERDASTRUM, in *Botany*, Baſtard Puff-ball, Mich. Gen. 219. t. 99. See SCLERODERMA.

LYCOPERDOIDES, Mich. Gen. 219. t. 98, a genus conſiſting of three ſpecies of fungi, very unlike each other. The firſt has a ſtout thick many-rooted ſtem, four inches high, and is the *Scleroderma tinctorium* of Perſoon, Syn. 152. The others are ſubterraneous productions, akin to the *Lycoperdon cervinum* of Linnæus.

LYCOPERDON, ſo called by Tournefort, from λυκος, *a wolf*, and περδὼ, *to explode backwards*, this author having certainly improved the old fooliſh name, *Crepitus lupi*, by making it leſs generally intelligible. We do not preſume to account for this curious appellation. The French call the fungus to which it is applied *Veſſe-loup*, or Wolf-bladder; the Engliſh *Puff-ball*; and the Germans *Boſiſt*; from which laſt Dillenius contrived the barbarous name *Boviſta*. Linn. Gen. 569. Schreb. 770. Mart. Mill. Dict. v. 3. Perſ. Syn. 140. Juſſ. 5. Tourn. t. 331. Lamarck Illuſtr. t. 887.—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eſſ. Ch. Caſe cauleſcent, burſting irregularly at the top, clothed with ſcaly or pointed warts.—(The powder or ſeed is greeniſh.) *Perſoon.*

The author laſt mentioned defines 14 ſpecies of this genus, very properly reſtricting it to ſuch fungi as anſwer to the above character, and excluding the ſtarry puff-balls, (ſee GEASTRUM); as well as the *Tuber*, the *Scleroderma*, and ſome others which Linnæus comprehended under his *Lycoperdon*. Examples are

L. *giganteum*. Perſ. n. 1. Batſch Fung. t. 165. (L. maximum; Schæff. Fung. v. 4. 130. v. 2. t. 191. L. Boviſta; Bulliard t. 447. L. Proteus; Sowerb. Fung. t. 332, two upper figures.)—This is often found as big as a man's head, in dry upland paſtures, in various parts of England and the ſouth of Europe. When the upper part, and the whole powdery contents, are blown away, the ſpongy baſe, with a thin torn edge, remains for a conſiderable time. The root is ſmall, but tough.

L. *pyriforme*. Perſ. n. 12. Schæff. Fung. v. 4. 128. v. 2. t. 185. (L. ovoideum; Bulliard t. 435. f. 3.)—Found on rotten ſtumps in beech woods in autumn. It is an inch and a half high, and an inch broad, tapering at the baſe, and pointed at the top, of a dirty browniſh-white.

L. *goſſypinum*. Perſ. n. 14. Bulliard t. 435. f. 1.—Found on rotten wood in France. A pretty ſpecies, about one-fourth of an inch in diameter, globoſe with a ſhort taper baſe, all over white or pale grey, and covered as it were with a fine down or cottony ſubſtance.

LYCOPERSICON, from λυκος, *a wolf*, and μηλον περσικον, *a peach*, the Tomato, or Love-apple, *Solanum Lycoperſicum* of Linnæus. This fruit is valued for its grateful acidity in Italy, Spain and Portugal, where it makes a principal ingredient in many ſoups and other diſhes, being moreover ſuppoſed to poſſeſs a ſtimulating, or aphrodiſiac property. Raiſed in England, its flavour is more inſipid, and its qualities not in any reſpect, as far as we have heard, remarkable; except that few ſtomachs can bear it in any great quantity. The fruit is beſt fried in ſlices, peppered and ſalted, as a ſauce for game or any roaſt meat.

LYCOPHRON, in *Biography*, ſon of Periander, king of Corinth, flouriſhed about five hundred and fifty years before the Chriſtian era. The murder of his mother Meliſſa, by his father, had ſuch an effect upon him, that he reſolved never more to ſpeak to him. This reſolution was ſtrengthened by their uncle Proclus, king of Epidaurus, who took Lycophron and his brother under his protection. When the infirmities of Periander obliged him to look for a ſucceſſor, Lycophron, who was then in the iſland of Corcyra, refuſed to come to Corinth while his father was there, and he was induced to promiſe to ſettle in that city, only on condition that his father would come and dwell on the iſland which he left. So fearful, however, were the Corcyrians of the tyranny of Periander, that they killed the ſon to prevent the meditated exchange from taking place.

LYCOPHRON, a famous Greek poet and grammarian, was born at Chalcis, in Eubœa, and flouriſhed about three hundred years before the Chriſtian era. He was one of thoſe poets who lived in the reign of Ptolemy Philadelphus, and who from their number obtained the name of Pleiades. According to Ovid he was ſlain by an arrow. He was author of ſeveral tragedies, of which the titles of twenty have been preſerved; but the only work that has come down to us, is a very ſingular poem, entitled "Alexandra," or Caſſandra, the ſubject of which is a ſeries of predictions feigned by him to have been uttered by that daughter of Priam. This poem contains 1474 verſes, the obſcurity of which has procured the epithet of "Tenebroſus" to its author. It is a mixture of prophetical effuſions, ſuppoſed to have been delivered by Caſſandra during the Trojan war. The beſt editions are that of Baſil, 1546, enriched with a commentary by Tzetzes; that of Canter, 1596; and that of our countryman, archbiſhop Potter, in 1702.

LYCOPHTHALMUS, the *wolf's eye-ſtone*, a name given by ſome authors to ſuch pieces of agate, or any other ſemi-pellucid ſtone, as happen to have circular ſpots in them, reſembling in colour the eye of that animal.

LYCOPODIOIDES, in *Botany.* See the following article.

LYCOPODIUM, from λυκος, *a wolf,* and πȣς, *the foot,* from the incurved, and often finger-like, ſhape of the ſpikes or extreme branches. Club-moſs, or Wolf's-claw.—Linn. Gen. 561. Schreb. 753. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1108. Swartz. Fil. 174. Brown Prodr. Nov. Holl. v. 1. 165. Juſſ. 12. Lamarck Illuſtr. t. 872. Michaux Boreal-Amer. v. 2. 282. Dill. Muſc. 441. (Lycopodioides; Dill. Muſc. 462. Selago; ibid. 435. Selaginoides; ibid. 460.)—Claſs and order, *Cryptogamia Muſci,* Linn. *Crypt. Miſcellaneæ,* Schreb. *Crypt. Filices,* Smith. *Crypt. Lycopodineæ,* Swartz.—Nat. Ord. *Muſci,* Linn. Dill. *Muſci ſpurii,* Juſſ. *Lycopodineæ,* Brown.

Eſſ. Ch. Capſules axillary, ſeſſile, naked, moſtly ſolitary, of one cell; ſome kidney-ſhaped, of two elaſtic valves, and full of fine powder; others two or three-lobed, of two or three valves, lodging from one to ſix globoſe bodies.

This beautiful and ample genus, one of the moſt elegant, with reſpect to habit, in the whole vegetable kingdom, holds as it were an intermediate place between the ferns and moſſes. Some botaniſts have therefore been moſt inclined to refer it to the one tribe, others to the other. Its habit, moſt like the moſſes, does yet by no means ſtrictly accord with that order; and their fructification, being now well underſtood, ſeparates them diſtinctly from *Lycopodium,* whoſe nature in that reſpect is almoſt totally in the dark, agreeing ſo far with ferns. The ſeeds of the latter, however produced, agree as nearly as can be with the powder found in the compreſſed or kidney-ſhaped capſules of the genus in queſtion, which powder moreover has been likewiſe proved, by experiment, to be real ſeed. But the globular bodies found in peculiar capſules upon *L. denticulatum* and other ſpecies, proved themſelves ſeeds by germinating, according to Brotero, Tr. of L. Soc. v. 5. 162, yet ſuch ſpecies are furniſhed beſides with what ſeems to be the genuine fruit of the genus. In this difficulty Profeſſor Swartz and Mr. Brown have prudently contented themſelves, in the generic character, with mentioning theſe two kinds of apparent capſules and ſeeds, without poſitively aſſerting either to be ſuch.

Joſeph Fox, a poor journeyman weaver of Norwich, is the firſt perſon upon record who ever raiſed plants of *Lycopodium Selago* from the duſt of the kidney-ſhaped capſules; ſee Tr. of Linn. Soc. v. 2. 314, where Mr. Lindſay's account of having ſucceeded equally well with the duſt of *L. cernuum* in Jamaica, is alſo to be found. Sprengel cites the authority of Profeſſor Willdenow in confirmation of this. We cannot but admit therefore that this duſt, ſo exactly reſembling the known ſeed of ferns, is real ſeed. This is the *Pulvis Lycopodii,* formerly kept in the apothecaries ſhops, on account of ſome reputed qualities long ſince diſbelieved. It is ſtill uſed in Germany to produce the appearance of lightning upon the ſtage; for being very light and highly inflammable, it takes fire inſtantaneouſly, with a ſort of hiſſing exploſion, while floating in the air. The duſt of *L. clavatum* is collected and ſold on the continent, for this purpoſe. With reſpect to the globular bodies, whoſe bulk is beyond all meaſure greater than that of theſe minute ſeeds, it is impoſſible to doubt the aſſertion of Profeſſor Brotero, who in the fifth volume of the Tranſactions of the L. Soc. deſcribes their germination, radicle, cotyledons, &c.; ſo that we muſt allow the exiſtence of two kinds of ſeed on the ſame plant. The ſame phenomenon has been ſuſpected in the genera *Fucus* and *Conferva,* though botaniſts have been ſo juſtly cautious of admitting it, that they have not dared to truſt their own eyes. Perhaps the actual exiſtence of the fact in *Lycopodium,* may ſanction our belief of it in theſe other inſtances. The difference however between theſe two kinds of ſeeds in *Lycopodium* is far more eſſential than Profeſſor Sprengel ſeems to inſinuate, when he ſays it "only proves that the capſules of ſeveral ſpecies of this genus are of two different ſhapes." (Crypt. 195, Engliſh tranſlation.) Nothing can be greater than the apparent difference betwixt the two kinds of ſeeds themſelves, which is ſuch as to overſet all analogy hitherto known. An idea advanced in Engl. Bot. v. 16. p. 1148, that the kidney-ſhaped capſules may be abortive ones, can hardly be admitted; for although we hear of no experiment made with the contents of the two different kinds of capſules from the ſame individual plant, (which if plants could be raiſed from both, would be truly an *experimentum crucis*;) yet the kidney-ſhaped capſules of the ſpecies in queſtion, *L. Selaginoides,* are too preciſely like thoſe from which vegetating ſeeds have been obtained, to allow of a doubt concerning them. We ought not to omit that Dillenius firſt obſerved theſe different kinds of ſeeds in *Lycopodium,* and has founded upon them the different genera into which he has divided it, as quoted among the ſynonyms above.

The 14th edition of *Syſt. Veg.* contains 29 ſpecies of *Lycopodium,* ſix of which are Britiſh. Profeſſor Swartz defines 65; excluſive of the Linnæan *nudum,* which he eſtabliſhes as a diſtinct genus, by the name of *Pſilotum;* as well as of ſeveral others, which he finds mentioned in books, but could not ſatisfactorily aſcertain.—Fifteen ſpecies have axillary ſeſſile capſules, all uniform, of two valves, containing the above-deſcribed powdery kind of ſeeds. The remaining 50 bear their capſules in terminal ſpikes, each capſule being accompanied by a peculiar ſcale or bractea, generally toothed or fringed, totally unlike the leaves, and moſtly of a paler or more tawny colour. Of theſe 50, 26 have the ſame kind of capſules and ſeeds as the above 15, and no other; one, (*L. Selaginoides,* Engl. Bot. t. 1148.) has, beſides ſuch capſules, very remarkable four-lobed ones, of two three-lobed valves, and containing four globoſe white ſeeds. The remainder have kidney-ſhaped as well as roundiſh, rarely three-lobed, capſules, either intermixed in the ſame ſpike, or the former are in the upper part, the latter in the lower. By this ſtatement it appears, that no known ſpecies is without the kidney-ſhaped compreſſed capſule, bearing the minute duſt-like ſeed, analogous to that of ferns; the larger globoſe ſeed being, as it ſeems, more of an adventitious nature.

Examples of the axillary ſpecies are,

L. *linifolium.* Linn. Sp. Pl. 1563. Sw. n. 1. (Selago linariæ foliis; Dill. Muſc. 440. t. 57. f. 5.)—Leaves alternate, remote, lanceolate.—Native of South America and the Weſt Indies. Taken up by Dillenius from Plumier, who in his *Filices,* t. 166. f. C, C, gives an original plate of this ſpecies, which no other botaniſt appears to have ſeen. The *root* is fibrous. *Stems* ſeemingly pendulous, above two feet long, ſlender, ſlightly branched, leafy throughout. *Leaves* ſcattered, half an inch at leaſt diſtant from each other, often near two inches long, entire, taper-pointed, ſomewhat ovate and twiſted at the baſe. *Capſules* axillary, ſolitary, kidney-ſhaped. No other known ſpecies can vie with this in the ſize and diſtance of its leaves.

L. *gnidioides.* Linn. Suppl. 448. Sw. n. 4.—Leaves three in a whorl, imbricated, ovato-lanceolate, obtuſe, entire. Branches elongated.—Gathered in the iſland of Mauritius by Sonnerat or Commerſon, and given by Thouin to the younger Linnæus. No other botaniſt ſeems to have ſeen the plant. It appears to be very tall, with the habit of the former, but differs eſſentially in its much cloſed and whorled *leaves*, not half an inch long, blunt and concave, without rib or vein; the upper ones very gradually ſhorter and more ovate, with ſolitary, paliſh, axillary, roundiſh, ſlightly reniforme, *capſules*.

L. *Selago*. Fir Club-moſs. Linn. Sp. Pl. 1565. Engl. Bot. t. 233. Sw. n. 12. Fl. Dan. t. 104.—Leaves ſcattered, in eight rows, ſomewhat imbricated, lanceolate, acute, rather concave. Stem forked, erect, level-topped.—Native of rather moiſt mountainous heaths; the only Britiſh ſpecies of this firſt ſection. The *ſtems* are about a ſpan high, beſet with dark, ſhining, fir-like *leaves*. *Capſules* ſmall, browniſh-yellow.

The ſpiked ſpecies are not only numerous, but, in many inſtances, remarkable for ſize and beauty. The Britiſh ones are *inundatum*, Linn. Sp. Pl. 1565. Engl. Bot. t. 239; *alpinum*, ib. 1567. E. Bot. t. 234;—*annotinum*, ib. 1566. E. Bot. t. 1727;—and the common *clavatum*, ib. 1564, E. Bot. t. 224.—This laſt grows abundantly on dry mountainous heaths, creeping on the ground to the extent of ſeveral feet; the fruit-bearing branches only being erect. Theſe bear one, two or three, finger-like denſe ſpikes of ovate, taper-pointed, membranous-edged, imbricated *bracteas*, each with an axillary ſolitary brown *capſule*.

Of the foreign ones none is more ſtriking than L. *Phlegmaria*. Linn. Sp. Pl. 1564. (L. erectum dichotomum, foliis cruciatis, ſpicis gracilibus; Dill. Muſc. 450. t. 61. f. 5.)—Leaves ovate or heart-ſhaped, entire; the lower ones four in a whorl. Spikes thread-ſhaped, forked.—This grows in various parts of the Eaſt Indies, as well as in the iſle of Bourbon. Mr. Menzies gathered our ſpecimen in Otaheite. It is 18 inches or more in height, ſlightly forked or branched, clothed with numerous ſhining *leaves*, not ſo regularly whorled, at leaſt the upper ones, as Dillenius found them. The long, terminal, ſlender, forked *ſpikes*, with their little roundiſh *bracteas*, ſcarcely broader than the accompanying *capſules*, are very ſingular.

Among the ſpecies with two ſorts of capſules is

L. *flabellatum*. Linn. Sp. Pl. 1568. (Lycopodioides dentatum erectum filicinum, caule tereti ramoſiſſimo; Dill. Muſc. 468. t. 65. f. 5. Muſcus ſquamoſus erectus; Plum. Fil. t. 43. Amer. t. 24.)—Leaves two-ranked, ovate, oblique, fringed at the baſe, accompanied by a double row of ſmaller imbricated ones in front. Stem round, repeatedly branched, flattened above.—The figures of this ſpecies, which is found in the Weſt Indies, give but an inadequate idea of its beauty. Its flat fan-like ſhape, and the exquiſitely neat arrangement of the innumerable little ſhining *leaves*, give it a peculiar and ſtriking aſpect. The *ſpikes* are ſmall, and ſparingly produced. *Root* fibrous. Whole *plant* from one to two feet high.

LYCOPOLIS, in *Ancient Geography*, viz. *the city of the Wolves*, an ancient town of Upper Egypt, in the Thebais, ſituated on the weſtern ſide of the Nile; ſo called, becauſe extraordinary worſhip was paid here to wolves, which, according to Diodorus Siculus, drove back the Ethiopians when they invaded Egypt, and purſued them to Elephantina, on the borders of Ethiopia. This city is ſuppoſed to have ſtood where the preſent town of Monfalut now ſtands.

LYCOPSIS, in *Botany*, ſo called by Pliny, being alſo the λυκοψις of Dioſcorides, owes its derivation to λυκος, *a wolf*, and οψις, *a face*, or *countenance*, from the circumſtance of the flowers being ringent, and having the appearance of a grinning mouth; the herbage is alſo furniſhed, ſays Ambroſinus, with a ſort of rigid hairineſs ſimilar to the coat of a wolf. Linn. Gen. 78. Schreb. 103. Willd. Sp. Pl. v. 1. 779. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 220. Ait. Hort. Kew. ed. 2. v. 1. 297. Juſſ. 131. Lamarck Illuſtr. t. 92. Gærtn. t. 67.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Aſperifoliæ*, Linn. *Borragineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five, oblong, acute, ſpreading, permanent ſegments. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, bent in a curve; limb five-cleft half way down, obtuſe; mouth cloſed, with five convex, prominent, uniting ſcales. *Stam.* Filaments five, very ſmall, placed at the curve of the tube of the corolla; anthers ſmall, covered. *Piſt.* Germens four, ſuperior; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma obtuſe, cloven. *Peric.* none, except the very large, inflated calyx. *Seeds* four, rather long.

Eſſ. Ch. Corolla with a curved tube, its mouth cloſed with convex ſcales.

Linnæus was acquainted with ſeven ſpecies of *Lycopſis*, to which Willdenow has added two more, L. *ciliata*, and *obtuſifolia*. This genus is particularly marked by the tube of the flowers being curved; indeed this circumſtance is conſidered by Linnæus and Willdenow as a ſufficient eſſential character. The following ſpecies will ſerve to illuſtrate the genus.

L. *pulla*. Dark-flowered Bugloſs. Linn. Sp. Pl. 198. Jacq. Auſtr. t. 188.—Leaves entire. Stem erect. Calyx, when in fruit, inflated, pendulous.—Found in fields and by road-ſides in Tartary and Germany, where it flowers from the beginning of May to July.—*Root* perennial, of nearly a finger's thickneſs, long, blackiſh. *Stem* about a foot high, roundiſh; ſimple below; dividing upwards into flowering branches. *Leaves* alternate, ſeſſile, ſoft, thickiſh, pale green. *Flowers* ſolitary; petals ſmooth, dark purple or nearly black, the tube reddiſh at its baſe, the limb marked with five ſunk dots at the bottom. *Seeds* roundiſh, ſomewhat rugoſe, ſticking to the pendulous and ſwelling calyx.

L. *arvenſis*. Small Bugloſs. Linn. Sp. Pl. 199. Engl. Bot. t. 938. Curt. Lond. faſc. 5. t. 17. Fl. Dan. t. 435.—Leaves lanceolate, briſtly. Calyx, when in flower, erect.—Very common in fields and waſte places all over England. It flowers in June and July.—The whole plant is hiſpid. *Stem* round, angulated, erect, branched. *Leaves* oblong heart-ſhaped, embracing the ſtem. *Cluſters* in pairs, terminal, leafy. *Flowers* ſmall, of a lively blue colour, with a white eye. *Seeds* angular, rugoſe, tuberculated. The juices of this plant are mucilaginous, like thoſe of Borage.

LYCOPUS is ſaid to be derived from λυκος, *a wolf*, and πους, *a foot*, though we are perfectly incompetent to trace the origin of ſuch a derivation. Linn. Gen. 15. Schreb. 20. Willd. Sp. Pl. v. 1. 120. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 29. Ait. Hort. Kew. ed 2. v. 1. 47. Brown. Prod. Fl. Nov. Holl. 500. Tournef. t. 89. Juſſ. 111. Lamarck Illuſtr. t. 18.—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, cloven half way down into five, narrow, acute, ſegments. *Cor.* of one petal, rather unequal; tube cylindrical, the length of the calyx; limb obtuſe, ſpreading in four, nearly equal diviſions; the upper one broader, emarginate; the lower ſmaller. *Stam.* Filaments two, generally longer than the corolla, inclining to the upper ſegment; anthers ſmall. *Piſt.* Germen ſuperior, four-cleft; ſtyle thread-ſhaped, ſtraight, as long as the ſtamens; ſtigma cloven, reflexed. *Peric.* none, except the calyx containing the ſeeds in its bottom. *Seeds* four, roundiſh, bluntiſh.

Eſſ. Ch. Corolla four-cleft; one of its lobes notched. Stamens diſtant. Seeds four, naked, blunt.

1. L. *europæus.* Water Horehound. Gypſywort. Linn. Sp. Pl. 30. Engl. Bot. t. 1105. Curt. Lond. faſc. 3. t. 2. —Leaves very deeply ſerrated.—Found abundantly on the banks of pools and ditches, in a ſandy ſoil, flowering in July and Auguſt.—*Root* perennial. *Stem* ſquare. *Leaves* oppoſite. *Flowers* white, many in a whorl. *Seeds* four, obovate, blunt, ſquare, furrowed.—The whole herbage is inodorous, though the flowers are ſometimes ſweet-ſcented. It varies occaſionally in having deeply pinnatifid leaves, more or leſs hairy; indeed they are ſcarcely ever quite ſmooth. Dr. Smith remarks that "the glandular dots, form of the corolla, and whole habit ſhew the affinity of this plant to *Mentha*;" but he thinks that the ſeeds would ſerve ſufficiently to diſtinguiſh it without adverting to the number of its ſtamens.

2. L. *exaltatus.* Italian Water Horehound. Linn. Suppl. 87. Willd. n. 2. Sm. Fl. Græc. Sibth. v. 1. 9. t. 12.—Leaves pinnatifid, toothed. Calyx four or five-cleft.—A native of Italy, and alſo of Greece in Lupadia and Bithynia, flowering in the ſummer.—*Root* perennial, creeping. *Stem* erect, from four to ſix feet high, leafy, hairy, often tinged with red. *Leaves* oppoſite, croſſing each other in pairs, deeply pinnatifid, hairy on both ſides. *Whorls* axillary, ſeſſile, denſe, many-flowered. *Bracteas* ſmall, linear-lanceolate, acute. *Corolla* tubular, white, a little longer than the calyx, mouth hairy. *Seeds* obovate, blunt, covered with reſinous dots, aromatic.

The pinnatifid variety of L. *europæus* has by ſome authors been confounded with the preſent plant; but on account of that ſpecies having a more humble ſtem, the ſegments of its leaves never toothed, and the calyx invariably five-cleft, Dr. Smith thinks they are ſufficiently diſtinct.

3. L. *virginicus.* Linn. Sp. Pl. 30. Michaux. Boreal-Amer. v. 1. 14.—Leaves ſtalked, elliptical, tapering at each end, equally ſerrated.—A native of America, from New England to Carolina. It flowers in the autumn.—The Linnæan ſpecimen of this ſpecies has *leaves* above an inch in breadth, with ſtrong, though not deep ſerratures. It therefore very ill agrees with the definition in *Flora Virginica*, "Leaves lanceolate, very finely ſerrated," or with Clayton's account, "Leaves long, narrow, and graſſy." It anſwers, however, exactly to Michaux's definition, "Leaves broadly lanceolate, ſerrated, contracted, and entire at the baſe."—The flowers are numerous, in denſe whorls. *Seeds* angular, each crowned with ſeveral blunt teeth.

Beſides the three ſpecies above deſcribed, Mr. Brown, in his Prodromus to the Flora of New Holland, mentions another, which he calls *auſtralis*, with the following character, "Leaves lanceolate, pointed, ſerrated, downy, roughiſh above, glandular beneath, entire, and attenuated at the baſe: ſerratures remote, equal, very acute. Stems ſtriated." This is found all over New Holland, and in Mr. Brown's opinion is very nearly allied to L. *europæus.* Michaux has another ſpecies under the name of *uniflorus*, which is thus characterized. "*Plant* very ſmall. *Root* tuberous. *Stems* ſimple. *Leaves* oval, obtuſe, obſoletely toothed. *Flowers* axillary, ſolitary." This is a native of North America.

LYCOSTAPHYLÆ, *wolf's grapes*, a name given by ſome of the Greek writers to the *pomum amoris*, a kind of eſculent nightſhade, which we have much more properly called *lycoperſicon*, the *wolf's peach.* (See SOLANUM.) Æmilius Macer tells, that the nightſhades, in general, were called by the name *morella* in his time: his words are, "herbam quam Græci ſtrychnum dixere, Latini morellam dicunt." The name *morella* ſeems to be formed upon the word *morion*, a name given both by the Greeks and Latins to one of the ſleepy nightſhades, and to the male mandrake of Dioſcorides, which the ſhepherds were fond of eating; but which brought on ſleepy diſorders, if taken too largely.

LYCOSTOMUS, in *Ichthyology*, the name given by Ælian, and many other of the Greek authors, to the *anchovy*, called by others the *encraulus* and *encrauſicholus*, and by the late writers *encraſicolus.* See CLUPEA *Encraſicolus*, and ANCHOVY.

LYCTOS, in *Ancient Geography*, a town ſituated in the interior of the iſle of Crete, and not far from Gnoſſus to the ſouth-eaſt. Of this town Polybius ſays, that it was a colony, originally of Lacedæmonians, and the moſt ancient of the Cretan towns, which produced men who were, without contradiction, the braveſt and moſt virtuous in the whole iſland. The priority of its exiſtence to Gnoſſus and Cortyna, however, has been doubted.

LYCURGIA, λυκουργεια, in *Antiquity*, a feſtival celebrated by the Spartans in memory of Lycurgus, whom they honoured with a temple, and an anniverſary ſacrifice.

LYCURGUS, in *Biography*, the celebrated legiſlator of Sparta, ſuppoſed to have been born about the year 926, was ſon of Eunomus, king of that country, and brother to Polydectes. He might have ſucceeded to the throne himſelf on the death of Polydectes, but knowing that the deceaſed king's widow was pregnant, he publicly declared that he would only hold the crown in truſt for the child, provided it ſhould prove a ſon. The queen, ambitious of retaining her place and dignity, propoſed to marry Lycurgus, and deſtroy the infant before its birth. Lycurgus took meaſures to prevent the completion of her wicked propoſals: ſhe was, in due time, delivered of a boy, which being brought to him, as he was ſitting at the table with the magiſtrates, he took it in his arms, placed it in the chair of ſtate, and exclaimed, "Here Spartans is your king." Lycurgus faithfully diſcharged the duty of regent and guardian during the minority of his nephew Charilaus, and as ſoon as the young prince came to years of maturity, he readily reſigned all authority into his hands, left Sparta, and travelled into ſeveral foreign countries, with the view of obſerving their laws and cuſtoms. He firſt viſited Crete, at that time governed by the laws of Minos: theſe laws he ſtudied moſt carefully, and contracted a friendſhip with Thales, whom he perſuaded to ſettle at Sparta. He thence paſſed over to Aſia, making obſervations on the principal Ionian cities, which were overwhelmed in luxury and effeminacy. Here he met with the works of Homer, which he tranſcribed and brought into Greece. The confuſion which followed his departure from Sparta, made his preſence again neceſſary, and he returned home at the earneſt ſolicitations of his countrymen. Perceiving that the diſorders of the ſtate admitted no other effectual remedy than a total change of the laws and conſtitution, he prepared to give a new legiſlative ſyſtem to Sparta. He took care to fortify his authority with the ſanctions of religion, and obtained from the oracle of Delphi a declaration, that the conſtitution he was about to eſtabliſh, would be the moſt excellent in the world. [For an account of his inſtitutions ſee the article LACÆDEMONIANS.] His principal object, as a patriot, was to render his country great and reſpectable among ſurrounding nations; this he attained, and Sparta, under the laws of Lycurgus, became a nation of invincible warriors, who, for a ſeries of years, bore the greateſt ſway in the affairs of Greece, and were the bulwark of their friends, and the dread of their foes. Lycurgus has been compared to Solon, the legiſlator of Athens, and it has been ſaid that the former gave his citizens morals conformable to the laws which he had eſtabliſhed, and that the latter had given the Athenians laws which coincided with their cuſtoms and manners. The office of Lycurgus demanded reſolution, and he ſhewed himſelf inexorable and ſevere. The Lacedæmonians ſhewed their reſpect for this great legiſlator by annually celebrating a feſtival in his honour, at which his praiſes were recited, and which was obſerved during ſeveral ages. It is not agreed in what manner, or when he died; according to Plutarch he voluntarily put an end to his life by abſtinence, while he was yet of an age to enjoy it. Lucian ſays he died at the age of eighty-five. The laws of Lycurgus were abrogated by Philopœmen in the year B.C. 188, but the Romans very ſoon re-eſtabliſhed them. Plutarch. Univer. Hiſt.

Lycurgus, an Athenian orator, ſon of Lycophron, flouriſhed in the time of Philip of Macedon, and is ſuppoſed to have died about the year 328 before Chriſt. He ſtudied philoſophy under Plato, and oratory under Iſocrates, and attaching himſelf to a political life roſe to eminence in the ſtate. The ſuperintendance of the public revenue was entruſted to him, in which office he conducted himſelf with the ſtricteſt integrity. He was appointed one of the magiſtrates, and in exerciſing the duties of his ſituation, he baniſhed all perſons of a diſſolute character, and made a number of very uſeful regulations. As he thought the higher kinds of poetry poſſeſſed ſuperior advantages, he patronized dramatic exhibitions, and cauſed ſtatues to be erected in honour of the principal tragedians. He was the friend of Demoſthenes, and a zealous advocate for liberty: when Xenocrates was dragged to priſon becauſe he had not paid the tribute exacted from ſtrangers, he liberated him and confined the farmer of the tax in his ſtead. Lycurgus was one of the thirty orators whom the Athenians refuſed to deliver up to Alexander. Some of his orations are preſerved, and have been printed in Collections of the Greek Orators. Plutarch. Lempriere.

LYCUS, in *Ancient Geography*, a river of Sarmatia, S.W. of Rhodus, which diſcharged itſelf into the Euxine ſea. It is mentioned by Ovid.—Alſo, a river, which, according to Herodotus, took its riſe in the country inhabited by the Thyſſagetæ, and traverſing that of the Mæotæ, ran into the Palus Mæotis. Ptolemy mentions this river, which is ſuppoſed to be the ſame with the preceding.—Alſo, a river of Aſia, in Phrygia.—Alſo, a river of Aſia Minor, in Caria, the ſource of which was in mount Cadmus, and it formed a lake in Latmicus Sinus.—Alſo, a river in Sicily, the ſame with Halycus.—Alſo, a river of Macedonia, mentioned by Plutarch.—Alſo, a river of Aſia Minor, in Myſia, in the canton of Pergamus.—Alſo, a river of Aſia, which proceeding from Armenia, watered the plain near the town of Heraclea, and diſcharged itſelf into the Iris.—Alſo, a river of Aſia, in Bithynia, the ſame with Rhyndacus, according to Pliny.—Alſo, a river of Aſia, in Pontus, which mixed its waters with thoſe of the Iris.—Alſo, a river of Aſia, in Cappadocia, according to Ptolemy, who ſays that it was one of the branches of the Abſorrus which fell into the Euxine ſea.—Alſo, a river of Aſia, in Aſſyria, according to Polybius and Ptolemy.—Alſo, a river of Aſia, in Syria, near the gulf of Iſſus, according to Pliny.—Alſo, a ſmall river of the iſle of Cyprus, which had its ſource in the interior of the iſland at mount Olympus, and diſcharged itſelf into the ſea to the weſt of Amathus.—Alſo, a river of Phœnicia, which ran between Byblos and Beryta, according to the Itinerary of Antonine.

LYDD, in *Geography*, a ſmall market-town in the hundred of Langport, in the lathe of Shepway, and county of Kent, England, occupies a low ſcite near the ſouth-weſtern extremity of the county, where a point of land running out into the ſea forms Dengeneſs bay, which, though very open, is of great ſervice for veſſels when the wind ſets violently from particular quarters. Leland ſays, “Lydde is counted as a part of Rumeney, is iii myles beyond Rumeney town, and is a market. The town is of a prety quantite, and the towneſch men uſe botes to the ſe, the which at this tyme is a myle of. The hole town is conteyned in one paroche, but that is very large. Ther is a place beyond Lydde, wher at a great numbre of holme trees groueth upon a banke of baches throwen up by the ſe: and ther they bat fowle, and kill many birdes.” The church, which is a ſpacious edifice, conſiſt of a nave, chancel, and aiſles, with a maſſive tower, ornamented with pinnacles at the weſt end. The monuments are numerous, and among them are many braſſes, chiefly for bailiffs and jurats of the town. Lydd is a corporate town by preſcription, and, like Romney, of which it is a member, is governed by a bailiff, jurats, chamberlain, and commonalty. The return under the population act of the year 1800 ſtated the number of houſes to be 204, that of the inhabitants 1303. The latter are chiefly engaged in fiſhing, and other maritime employments, of which ſmuggling is conſidered as forming a material branch. Lydd is 71 miles diſtant from London; has a ſmall market on Thurſdays, and an annual fair. The holm trees, or ſea hollies, mentioned by Leland, ſtill grow on the beach near the town.

On the point of land called Dengeneſs, is a light-houſe, 110 feet high, erected a few years ago, in place of a more ancient one, under the direction of Mr. James Wyatt, and partly on the model of the Eddyſtone light-houſe. This point is alſo defended by a fort, and ſeveral ranges of barracks have been erected in the vicinity. Beauties of England and Wales, vol. viii.

LYDDA, in *Ancient Geography*, a town of Judæa, in the tribe of Ephraim; which was one of the three towns that Demetrius, king of Syria, compelled the Samaritans to ſurrender to the Jews; it was alſo called Dioſpolis.

LYDGATE, John, in *Biography*, an early Engliſh verſifier, and a monk of the Benedictine abbey at St. Edmund's Bury, in the reign of Henry VI. He was educated partly at Oxford, and then travelled into foreign countries to acquire the learning of the times. He was the diſciple and friend of Chaucer, and was regarded as a prodigy of learning at the period in which he flouriſhed, and is ſaid to have been a good poet and rhetorician, geometrician, aſtronomer, and theologian. He opened a ſchool in his monaſtery for teaching the ſons of the nobility the arts of verſification and compoſition. He was an imitator of his maſter Chaucer, but is reckoned among thoſe who contributed to the improvement of the Engliſh language. His principal pieces are “The Fall of Princes,” from the French of Boccaccio; “The Story of Thebes,” chiefly from Guido Colonna; and “The Troy Boke,” or “Deſtruction of Troy.” Beſides theſe, a liſt has been given of his other pieces, amounting to 251, exiſting in MS. in different libraries.

LYDIA, in *Ancient Geography*, firſt called Mæonia, from Meon, king of Phrygia and Lydia, and afterwards Lydia, from Lydus, the ſon of Atys, one of its kings. Bochart, who denies the exiſtence of ſuch perſons as Meon and Lydus, derives the name Lydia from the Phœnician word *luz*, to wind, becauſe it lay on the banks of the Mæander, a river famous for its windings, and Mæonia, from a Greek tranſlation of the Phœnician word *lud*. Lydia and Mæonia are ſometimes diſtinguiſhed; that part where mount Tmolus ſtood, watered by the Pactolus, being properly called Mæonia, and the other lying on the coaſt of Lydia. Lydia, according to Pliny, Ptolemy, and other ancient geographers, was bounded by the Myſia major on the north, by Caria on the ſouth, by Phrygia major on the eaſt, and Ionia on the weſt. But the kingdom of Lydia, as the ancients underſtood it, extended from the river Halys to the Ægean ſea. The chief cities of Lydia were Sardis, the ſeat of king Crœſus, Philadelphia, formerly the ſecond city of Lydia, Thyatira, a colony of the Macedonians, and Magneſia, ſeated on the Mæander. The only mountain of any note in Lydia is Sipylus. Mount Tmolus was once very famous for its wine and ſaffron. The rivers of this country, moſt worthy of notice, are the Pactolus and the Cayſter.

As to the origin of the Lydians, Joſephus, and almoſt all eccleſiaſtical writers after him, derive them from Lud, the fourth ſon of Shem, an opinion founded merely on the ſimilarity of names. Some of the ancients ſuppoſe them to be a mixed colony of Phrygians, Myſians, and Carians. Others, finding ſome conformity in religion between the Egyptians and Tuſcans, who were a Lydian colony, conclude that they were originally Egyptians. Their fables, however, ſhew that they were a very ancient nation, and of their high antiquity there is ample evidence.

The Lydians began, at a very early period, to be governed by kings, whoſe ſovereignty ſeems to have been deſpotic, and the crown hereditary.

Of their kings there are three diſtinct races on record, *viz.* the Atyadæ, ſo called from Atys, the ſon of Cotys and grandſon of Manes; the Heraclidæ, or deſcendants of Hercules, who began to reign about the time of the Trojan war; and the Mermnadæ, who began to reign not long before the Medes ſhook off the Aſſyrian yoke, of which race the firſt king was Gyges, and the laſt Crœſus. As to the character of the Lydians, they were under Crœſus, and ſome of his predeceſſors, a very warlike people; but when ſubdued by the Perſians, and enjoined by Cyrus, according to the advice given him by Crœſus, to wear long veſts, and to apply themſelves to ſuch arts only as had a natural tendency to debauch their manners, and enervate their courage, they became voluptuous and effeminate, unfit for action, and wholly given up to idleneſs, pleaſure, and diverſions. The ſoil of this country, watered by many rivers, was very fruitful; abounding with all ſorts of grain, and celebrated for its exquiſite wines. It was alſo enriched with ſeveral mines, whence Crœſus is ſaid to have drawn his immenſe wealth.

As to the religion of the Lydians, it ſeems to have been much the ſame with that of the Phrygians. They worſhipped Diana, Jupiter, and Cybele at Magneſia. The cuſtoms of the Lydians were ſimilar to thoſe of the Greeks, except that they uſed to proſtitute their daughters, who had no other fortune except what they earned in this way. They puniſhed idleneſs as a crime, and inured their children from their infancy to hardſhips. Their arms were not bows and arrows, but long ſpears anciently uſed by the cavalry; and if we may believe Herodotus, the Lydians far excelled all other nations in horſemanſhip. They were the firſt that introduced the art of coining gold and ſilver, for facilitating trade; the firſt that ſold by retail, that kept eating-houſes and taverns, and that invented public ſports and ſhows, which were therefore called *ludi* by the Romans, who borrowed them of the Tuſcans, the deſcendants of the Lydians. To theſe diverſions they recurred for relief at a time, during the reign of Atys, when a great ſcarcity of proviſions prevailed through the whole kingdom of Lydia. Having contrived various kinds of diverſions, as Herodotus informs us, they uſed to play one whole day without intermiſſion, eating and drinking the next day without other amuſement. After they had continued thus alternately faſting and feaſting, and finding that their calamities increaſed rather than abated, the king divided the whole nation into two bodies, commanding them to determine by lot, which of the two ſhould remain at home, and which ſhould go abroad in queſt of new habitations, ſince their native country could not afford them ſufficient maintenance. Thoſe who by lot were conſtrained to abandon their country, after many adventures, arrived in that part of Italy, which was then called Umbria, and is now named Tuſcany. Thus they changed their name, being no longer called Lydians, but Tyrrhenians, from their leader Tyrrhenus.

Although the trade of the Lydians is no where particularly mentioned, we may well imagine that it was conſiderable, eſpecially under their latter kings, when Lydia was in the meridian of its glory; on account of the ſplendour of this monarchy and the advantageous ſituation of the country. The ſame inference is juſtified by adverting to the immenſe riches, not only of the Lydian princes, but of ſeveral private perſons. Herodotus (lib. vii. c. 23.) mentions one, named Pythius, who not only entertained Xerxes and his whole army, while he was marching with innumerable forces to invade Greece, but made him an offer of 2000 talents of ſilver, and 3,993,000 pieces of gold, bearing the ſtamp of Darius. This ſame Pythius was reckoned the richeſt man in the then known world. The laſt king of Lydia was Crœſus (ſee his article), with whoſe capture by Cyrus at the ſiege of Sardis (B.C. 548.) the ancient kingdom of Lydia terminated; and from this time it continued ſubject to the Perſians, till they alſo were conquered by the Macedonians. Anc. Un. Hiſt. vol. iv.

LYDIAN, the name of one of the modes in Greek muſic, which occupied the middle place between the Æolian and Hypodorian. It was alſo ſometimes called the Barbarian mode, from its being invented by a people of Aſia. See Mode.

Euclid diſtinguiſhes two Lydian modes; that of which we have been ſpeaking, and another called a low Lydian, and which is the ſame as the Æolian mode, at leaſt as to its fundamental. The character of the Lydian mode was animated and intereſting, yet melancholy, pathetic, and proper for voluptuous occaſions; on which account Plato baniſhed it his republic. It was ſaid that by this mode Orpheus tamed wild beaſts, and that Amphion built the walls of Thebes. Some ſay that it was invented by Amphion, the ſon of Jupiter and Anthiope; others by Olympus the muſician, and diſciple of Marſyas; while there are ſtill others who aſſign it to Melampides. Pindar ſays, that it was firſt uſed at the nuptials of Niobe.

Lydian *Games*, was a name given to the exerciſes and amuſements invented by the Lydians: they are ſaid to have invented the quoit and games of chance, played with dice. Theſe Aſiatics, after they had loſt their city, emigrated into Etruria, whither they carried their ceremonies and games. Some Romans, having a paſſion for foreign play, adopted the Lydian method of gaming, which in the time of the emperors was purſued with ſuch exceſs, that Juvenal is very ſevere on the great number of thoſe who were haſtening to ruin by that means.

The Lydian games were at firſt called *Lydi* by the Romans, but afterwards, by corruption, *Ludi*.

Lydian *Lyre*, in the *Ancient Muſic*. The Trigon inſtrument or harp of the Aſiatics or Barbarians was uſually ſo called.

Julius Pollux, c. 10 of l. iv. Onomaſt. ſpeaks of a Lydian harmony, mode or tune, proper for the flute, of which he aſcribed the invention to Anthippus; and a little further, he ſays, that the Lydian nome proper for the flute was invented by Olympus or Marſyas.

For the ſcale and names or characters of the notes in the Lydian mode, ſee Music *of the Greeks*, and Notation. The Lydian mode correſponded with our key of E.

Lydian *Stone*; *Lydiſcher ſtein*, Wern.; *Baſanite*, Kirw.; *Pierre cornéenne* of ſome French mineralogiſts; vulgarly *Touch ſtone*, *Black jaſper*, &c.

Its colour is commonly greyiſh-black, which ſometimes approaches to blueiſh and velvet black.

It is found maſſive and in irregular blunt-edged rolled pieces, ſometimes traverſed by veins of quartz, which are however more frequently ſeen in the common flint-ſlate, of which the Lydian ſtone is conſidered to be a ſubſpecies.

Externally ſmooth and gliſtening; internally it is more or leſs glimmering. Its fracture is even, approaching to flat conchoidal, and alſo ſometimes to uneven and ſplintery; in the large it paſſes into ſlaty. Fragments indeterminately angular, moſtly ſharp-edged; they are opaque, ſeldom tranſlucent at the edges.

It is hard, but leſs ſo than quartz; brittle; not very eaſily frangible. Specific gravity 2.596, Kirwan; 2.880, Groſs; 2.887, Gerhard.

The Lydian ſtone is, like the common flint-ſlate, infuſible *per ſe*; and it generally retains its black colour in a very intenſe heat.

With regard to its geognoſtic ſituation it differs conſiderably from the common *Flint-ſlate* (which ſee); for it does not, like this, form entire mountains, but only ſingle ſtrata. Thus it occurs alternating in uniform ſtrata with primitive clay ſlate, in Saxony, Bayreuth, &c. To Mohs, however, it appears to be only the newer clay-ſlate formation which contains ſuch ſtrata; ſince the older clay ſlate of the lofty ridges of mountains in the Saxon Erzgebirge appears to be entirely deſtitute of Lydian ſtone. In ſecondary formations, ſuch as the greywacke mountains, it occurs partly as rolled pieces (being the products of a deſtroyed older formation), partly in beds in uniform ſtrata alternating with greywacke and greywacke ſlate: of this latter numerous examples occur in the Hartz mountains. Of the older formation of this rock, it is worth remarking that it occurs with traces of carbone.

The beds of Lydian ſtone, where they baſk out, appear very much rent, and divided into cubic maſſes; and, indeed, this cubic form is ſtill more or leſs diſcernible in the boulders and rolled pieces of this ſubſtance found in brooks and rivers. Mohs.

LYDIAT, Thomas, in *Biography*, an Engliſh mathematician, was born at Okerton, in Oxfordſhire, in 1572, and was educated at Wincheſter-ſchool, from whence he removed to New college, Oxford, where he obtained a fellowſhip. He applied himſelf with great aſſiduity to the ſtudy of the languages, philoſophy, aſtronomy, the mathematics, &c. In the year 1603 he reſigned his fellowſhip, and contented himſelf with living on his patrimonial eſtate. The next ſeven years he ſpent in publiſhing ſeveral books which he had begun in the college, particularly his "Emendatio Temporum ab initio mundi huc uſque compendio facta, contra Scaligerum." This work was dedicated to Henry, prince of Wales, who appointed him his chronographer and coſmographer. In 1609 he became acquainted with archbiſhop Uſher, who gave him a ſituation in the college at Dublin, which he held about two years. In 1612 he was preſented to the rectory of Okerton. He was a great ſufferer for his loyalty in the civil wars: at one time he was ſo completely ſtripped of all his property, that for three months together he was under the neceſſity of borrowing a ſhirt, to be able to change his linen. He was twice forced away from his own houſe, and once made a priſoner in Warwick caſtle. He died extremely poor in 1646, when he was about 74 years of age. In 1669 a ſtone, with an inſcription, was placed over his grave, at the expence of the fellows and wardens of his college: an honorary monument was likewiſe erected to his memory. He was a perſon of ſmall ſtature, but of great parts, and of a public ſoul: he was a man of conſiderable and various erudition, and held in high eſtimation by learned men both at home and abroad. He wrote a great number of books, beſides that already referred to, as 1. "De variis annorum formis," and a defence of the ſame in reply to Clavius and Scaliger. 2. "On the Origin of Fountains." 3. Several treatiſes on Philoſophy and Aſtronomy, &c. He left behind him a number of MSS.

LYDOWIARY, in *Geography*, a town of Samogitia; eight miles N.W. of Roſienne.

LYE, in *Agriculture*, any watery fluid much impregnated with ſaline matter. In huſbandry the term is generally applied to ſuch fluids as are employed for the purpoſe of ſteeping grain; in which caſes the beſt criterion of their ſtrength is that of the ſwimming of an egg. See Steep.

Lye, Edward, in *Biography*, a learned antiquarian, and great maſter of the Gothic and Saxon tongues, to whoſe labours we have had frequent occaſion to refer, was born at Totneſs, in Devonſhire, about the year 1694, where his father kept a ſchool. He was educated at home till he was about nineteen years of age, when he was admitted at Hertford college, Oxford: here he took his degrees, and in 1719 was ordained prieſt, and preſented to the living of Haughton-parva, in Northamptonſhire. In this ſituation he employed himſelf in the profound ſtudy of the Anglo-Saxon language. His firſt publication was an edition of the "Etymologicum Anglicanum" of Francis Junius, from the author's MS. in the Bodleian library. To this he prefixed an Anglo-Saxon grammar. In 1750 he was preſented to the vicarage of Yardley-Haſtings. After this he publiſhed the Gothic goſpels, with a Gothic grammar prefixed to them: but the great labour of the latter part of his life was his Anglo-Saxon and Gothic dictionary, which he had juſt finiſhed and put to preſs, when death terminated his labours in 1767. It was publiſhed under the direction of the Rev. O. Manning in 1772.

LYEMMER. See Leviner.

LYGDINUM Marmor. See Marble.

LYGDUS Lapis, in *Natural Hiſtory*, a name given by ſome of the ancients to the ſpecies of alabaſter, which others of them called *marmor lygdinum*, by which name there is only one ſpecies.

LYGE, in *Geography*, a town of Norway, near a lake of the ſame name; 16 miles N.W. of Chriſtianſand.

LYGEUM, in *Botany*, one of Loefling's genera, and ſo called from λυγος, *a rod* or *twig*, in alluſion to the tough pliant ruſhy nature of the plant. Loefl. It. 284. t. 2. Linn. Gen. 31. Schreb. 43. Willd Sp. Pl. v. 1. 316. Mart. Mill. Dict. v. 3 Ait. Hort. Kew. ed. 2 v. 1. 135. Juſſ. 33. Lamarck Illuſtr. t. 39. Richard in Sims and Kon. Ann. of Bot. v. 2. 548. t. 15 — Claſs and order, *Triandria Monogynia.* Nat. Ord. *Gramina.*

Gen. Ch. *Cal.* Glume of one ovate, convoluted, pointed, permanent valve, at length inflexed, ſeparating at the lower ſide, and containing two equal, oppoſite, parallel, level florets. *Cor.* of two valves, very hairy at the baſe, permanent; the outermoſt ovate, pointed, convex, awnleſs; inner twice as long, linear, narrow, acute, cloven at the ſummit, awnleſs. *Stam.* Filaments (in each floret) three, equal, longer than the corolla, flattiſh, very narrow, anthers vertical, linear, cloven at each end. *Piſt.* Germen ſuperior, oblong, convex at the outſide, flat at the inner; ſtyle ſimple, compreſſed, the length of the ſtamens; ſtigma ſimple, taper-pointed, incurved. *Peric.* none, except the hardened hairy baſe of the corolla of each floret, united longitudinally to the other. *Seeds* ſolitary, linear-oblong, convex at the outſide, flattiſh, with a longitudinal furrow, at the inſide.

Eſſ. Ch. Glume of one valve, convoluted, two-flowered. Corolla of two valves, the innermoſt twice as long as the outer, awnleſs. Seed ſolitary, encloſed in the hardened combined baſe of each floret.

1. L. *Spartum.* Baſtard Mat-weed. Linn. Sp. Pl. 78. (Sparta herba alterum; Cluſ. Hiſt. v. 2. 220. Spartum alterum Plinii; Ger. em. 41.)—The only known ſpecies obſerved by Loefling to be very abundant in the ſouth of Spain, always growing in low places, on a clay ſoil, where the water ſtands after much rain. The Spaniards call it *Albardin,* or *Alvardin,* a name probably retained from the Moors. The *root* is creeping and perennial. *Stems* about a ſpan high, erect, ruſhy, round, ſlender, ſmooth, nearly naked, with one joint, above which they are much extended after flowering. *Leaves* ſeveral, ſheathing the lower part of the ſtem, and about equal to it in height, narrow, convoluted, taper-pointed, ruſhy, ſmooth; the upper or floral one ſhorter, with a longer ſheath. *Stipula* thin, membranous, oblong, cloven, decurrent. *Flower* large, terminal, ſolitary, at firſt erect, inclining as the ſeeds ripen, with a knot at the baſe. *Calyx* ſmooth, delicately ſtriped with green, at length opening and expoſing the long denſe hairs which clothe the baſe of the permanent corolla, inveſting the ſeed.

The error of Linnæus and Loefling, who ſuppoſed the germen to be inferior, and common to two florets, is properly corrected by Richard, who ſhews the ſuppoſed two-celled nut to be formed merely of the hardened combined baſes of the corollas of the two florets. This is analogous to many other true graſſes, (as this is,) whoſe hardened corolla becomes a huſk or ſhell to the ſeed. In other points the deſcription of Richard is ſcarcely, if at all, ſuperior to that of Loefling.

This plant, being far inferior in tenacity, as well as length, to the true *Spartum* or Mat-weed, *Stipa tenaciſſima* of Linnæus, ſerves chiefly in Spain for ſtuffing mattraſſes. It flowers in May and June, ripening ſeed in autumn, and often retaining its empty ſheath or calyx till the following ſummer. The parts of fructification are, on the whole, perhaps larger than thoſe of any other graſs.

LYGINIA, from λυγινος, *twiggy,* alluding to its hard tough ruſhy habit. Brown Prodr. Nov. Holl. v. 1. 248. (Schoenodum; Labillard. Nov. Holl. v. 2. 79.)—Claſs and order, *Dioecia Monadelphia.* Nat. Ord. *Tripetaloideæ,* Linn. *Junci,* Juſſ. *Reſtiaceæ,* Brown.

Eſſ. Ch. Male, Spatha of one valve. Petals ſix. Filaments united lengthwiſe. Anthers three, didymous, cloven at each end.

Female, Spatha of one valve. Petals ſix. Style in three deep diviſions. Capſule three-lobed, three-celled, burſting at the prominent angles. Seeds ſolitary.

The root is ſcaly, creeping, with thick downy fibres. Stems ſimple, round, leafleſs, with ſeveral ſheathing ſcales, eaſily breaking at the joints. Spike terminal, of ſeveral crowded tufts of flowers, each accompanied by a common ſheathing bractea, the female flowers ſometimes ſolitary.

1. L. *imberbis.* Bracteas and ſpathas beardleſs. Male and female tufts many-flowered.—Native of the ſouth part of New Holland.—This is *Schoenodum tenax,* the male plant, of Labillardiere, t. 229. f. 1. Mr. Brown obſerves, that this ſuppoſed ſpecies of the French author is made up of two different genera; he therefore thinks it ſafer to reject the generic name entirely, than to retain it for either the male or female plant, which might lead to error. To this determination we gladly aſſent, eſpecially as the ſaid name, being compoſed of another eſtabliſhed one, *Schoenus,* is abſolutely inadmiſſible, and its termination being altered for the worſe from *Schoenoides,* (which the author gives as his meaning) not in any manner removing the objection.

2. *L. barbata.* Bracteas and ſpathas bearded. Male tufts of few flowers; female ones ſingle-flowered, nearly ſolitary. From the ſame country. Theſe plants have much of the habit of *Reſtio, Elegia,* &c. See Lepyrodia.

LYGISMOS, from λυγιζω, *to diſtort,* in *Surgery,* a diſtortion of the limbs; ſometimes a luxation.

LYGMOS. See Hickup.

LYGODIUM, in *Botany,* from λυγωδης, *pliant, tough,* and *ſlender,* expreſſive of the habit of this elegant genus, which conſiſts of ferns with twining ſtems. Swartz Syn. Fil. 152. Sim's and Konig's Annals, v. 2 305. t. 1. f. 2. Sprengel Crypt. 176. t. 5. f. 39. Brown Prodr. Nov. Holl. v. 1. 162. Bernhardi in Schrad. New Journ. v. 1. faſc. 2. 39. t. 3. (Ugena; Cavan. Leccion. 551. Hydrogloſſum; Willd. Abhandl. 20. t. 1, 2. Odontopteris; Berhardi in Schrad. Journ. for 1800. 127. t. 2. f. 4. Giſopteris; ibid 129. t. 2. f. 1. Ramondia; Mirbel Bull. des Sciences an 9. 179.)—Claſs and order, *Cryptogamia Filices.* Nat. Ord. *Filices,* Linn. Juſſ. *Filices Oſmundaceæ,* Brown.

Gen. Ch. *Capſules* without a ring, ovate, reticulated with veins, pellucid, radiated with furrows at the top, burſting lengthwiſe, ſeſſile, reverſed, attached by their middle, in two rows, on narrow proceſſes of the frond at its back, forming little, ſimple or forked, ſpikes. *Involucrum* conſiſting of ſeparate ſcales, alternate with the capſules, originating from the veins of the frond, unconnected at their upper part.

Eſſ. Ch. Capſules ſeſſile, ovate, attached by their middle, reverſed, radiated at the top, in two rows on the back of narrow proceſſes of the frond. Involucrum of ſolitary ſcales, ſeparating the capſules.

Obſ. Mr. Brown has firſt remarked the great peculiarity of the inſertion of the capſules, they being attached by their middle, not by their baſe. The ſtem is long, twining, and climbing. Leaves in pairs, on one common cloven footſtalk, each of them either divided or compound. Fructification either fringing their lobes in the form of minute, pale, chain-like ſpikes, or rarely compoſing the whole of certain leaves, transformed as it were into a compound forked aſſemblage of ſpikes. See Willd. t. 1. f. 2.

Swartz defines eleven ſpecies, to which Mr. Brown adds a twelfth, found in the tropical region of New Holland, which he calls *L ſemibipinnatum.*

Beautiful ſpecimens are

L. *ſcandens.* Sw. n. 1. (Ophiogloſſum ſcandens; Linn. Sp. Pl. 1518. Ugena ſemihaſtata; Cav. Ic. v. 6. 74. t. 594. f. 1. Adiantum volubile minus; Rumph. Amb. v. 6. 75. t. 32. f. 2, 3. Filix; Petiv. Gazoph. t. 64. f. 11.)—Stem round. Fronds pinnate. Leaflets ſtalked, oblong; heart-ſhaped or lobed at the baſe: the barren ones finely ſerrated.—Native of the Eaſt Indies, and of Brazil. This riſes to the height of ſeveral feet.—The *fronds* or branches ſpring in pairs from a woolly-topped knob, and are each a ſpan long, of about eight or ten alternate, ſtalked, oblong leaflets, with an odd terminal one of larger ſize. Each is fringed with numerous ſhort, rather hairy, ſpikes.

L. *circinnatum.* Sw. n. 6. (Ophiogloſſum circinnatum;

Burm. Ind. 228. O. flexuoſum; Linn. Suppl. 443, not Sp. Pl. 1519. Adiantum volubile polypoides, ſive majus; Rumph. Amb. v. 6. 75. t. 33.) — Stem round. Fronds palmate, in three or four lanceolate entire taper-pointed lobes; the fertile ones much contracted.—Native of the Eaſt Indies. We have it from Tranquebar.—The *leaves* are deeply palmate, ſmooth, entire, pale green. *Spikes* marginal, very ſhort, almoſt round.

Linnæus confounded this with the *Valli-panna*, Hort. Malab. v. 12. 63. t. 32, which ſeems to be his real *O. flexuoſum*, and is *Lygodium flexuoſum* of Swartz, n. 5.

LYGON and Lygus, are uſed for agnus caſtus.

LYGUM, in *Geography*, a town of Denmark, in the duchy of Sleſwick; 14 miles W. of Apenrade.

LYING-IN Hospital. See Hospital.

Lying-in *Women, Diſorders of.* See Labour, Lochia, Fever, After-pains, &c.

Lying-in *Women, Treatment of.* See Labour.

Lying *under the Sea*, in *Sea Language*, is when, in a ſtorm, the ſhip is a-hull, and the helm ſo faſtened a-lee, that the ſea breaks upon her bow, or broadſide.

Lying *along*, denotes the ſtate of a ſhip, when preſſed down ſideways by a weight of ſail in a freſh wind that croſſes the ſhip's courſe either directly or obliquely.

Lying-*to*, or *Lying-by*, denotes the ſituation of a ſhip when ſhe is retarded in her courſe, by arranging the ſails in ſuch a manner, as to counteract each other with nearly an equal effort, and render the ſhip almoſt immoveable, with reſpect to her progreſſive motion or head-way.

A ſhip is uſually *brought-to* by the main or fore-top-ſails, one of which is laid a-back, whilſt the other is full; ſo that the latter puſhes the ſhip forward, whilſt the former reſiſts the impulſe, by forcing her a-ſtern. This is particularly practiſed in a general engagement, when the hoſtile fleets are drawn up in two lines of battle oppoſite to each other: it is alſo uſed to wait for ſome other ſhip, either approaching or expected; or to avoid purſuing a dangerous courſe, eſpecially in dark or foggy weather, &c. Falconer.

Lying-*to in a Storm.* See Trying

LYKSBORG, or Luxburg, in *Geography*, a town of Denmark, in the duchy of Sleſwick, on a promontory near the Baltic; 7 miles N.E. of Flenſborg.

LYKSALE, a town of Sweden, in the Lapmark of Umea; 80 miles S.S.W. of Umea

LYMAN, a townſhip of America, in Grafton county, New Hampſhire, ſituated at the foot of a mountain on the eaſt ſide of Connecticut river, between Littleton and Bath, 7 miles W. by N. of New Concord; incorporated in 1761, and containing 533 inhabitants.—Alſo, a town in the county of New York, Maine, north of Wells and eaſt of Alfred, to each of which it adjoins.

LYME, a town of Grafton county, New Hampſhire.—Alſo, a poſt-town in New London county, Connecticut, the "Nehantick" of the Indians, at the mouth of the Connecticut river, on its eaſt ſide; ſettled about the year 1664, and incorporated in 1667; and containing, in three pariſhes, 4380 inhabitants.

LYME REGIS, a ſea-port, borough, and market-town, in the hundred of Whitchurch, in Bridport diviſion of Dorſetſhire, England, is ſituated 23 miles diſtant from Dorcheſter, and 143 from London, on the little river Lyme, near the ſea. Its ſituation, in a cavity between two rocky hills, on a declivity, makes it difficult of acceſs; and that part of the town neareſt to the ſea is ſo very low, that at ſpring-tides the under-rooms and cellars are overflowed to the depth of ten or twelve feet. Lyme is mentioned in hiſtory in the eighth century, when Cenwulf, king of the Weſt Saxons, granted, in a charter to the church of Sherborne, "the land of a manſion near the weſt bank of the Lim, ſo that ſalt for the ſaid church ſhould be boiled there." In the Domeſday Survey we find the manor of Lyme as being in three diviſions or parcels. Edward I. granted Lyme the liberties of an haven and borough; and from that period it increaſed in buildings, and became ſo proſperous, that it was able to furniſh Edward III. with four ſhips, and ſixty-two mariners, for the ſiege of Calais. In the reigns of Henry IV. and V., the ſouthern coaſt of England was much annoyed by the incurſions of the French: this town ſeverely experienced their effects; and being alſo afflicted by other caſualties, its trade declined conſiderably. It has ſince been occaſionally retrieved and reduced; but is now recovering its importance through the reſidence of merchants, who have recently erected ſome handſome ſtone-houſes; and as the harbour is conſidered one of the beſt in England, the town is capable of great improvement. During the civil war in the reign of Charles I., Lyme was a place of great conſequence to the contending parties, eſpecially to the royaliſts; great part of their dependence on the weſt of England ariſing from being in poſſeſſion of this town. The ſiege of Lyme was one of the moſt remarkable that occurred during that eventful period. In the reign of James II., Lyme was diſtinguiſhed by the landing of the duke of Monmouth here on his unfortunate contention for the kingdom, and by the ſanguinary executions which took place on his defeat.

The privileges granted by Edward I. to this town have been confirmed and increaſed by ſeveral ſucceeding ſovereigns. The corporation conſiſts of a mayor, who acts as a juſtice in the years before and after his mayoralty, a recorder, town-clerk, and fifteen capital burgeſſes, of whom two with the mayor are juſtices. The royalty of the manor is veſted in the corporation. Lyme has been repreſented in parliament ever ſince the twenty-third year of Edward I. The right of election is in the mayor, burgeſſes, and freemen; the voters being between thirty and forty. The church is a neat, though ancient edifice, but is not particularly worthy of notice. The cuſtom-houſe is a modern brick building, ſupported on pillars, for the convenience of the corn-market, which is held beneath. The quay is commodious, though not ſpacious; and round the harbour are ſeveral ſmall forts mounted with cannon for its defence. The principal public work, however, is the cobb, or pier, which, in its ancient ſtate, was compoſed of vaſt pieces of rocks rudely piled on each other; but is now formed of ſtone. This is a fabric of the greateſt utility on this coaſt, there being no other ſhelter for ſhipping between the Start point and the Portland road; and although at this place the ſouth-weſt wind blows with extreme violence, veſſels ride in the harbour in perfect ſecurity. The cobb has ſuffered very much by theſe winds: it was totally deſtroyed in the reign of Richard II.; and in the laſt century it ſuſtained great injury by three ſtorms, but was repaired by government at the expence of 6000*l.* Charles II. granted 100*l.* *per annum* towards its repair, out of the cuſtoms of the port, which is ſtill continued; and the inhabitants annually chuſe two cobb wardens to ſuperintend the improvement. The population of this town, in the year 1801, was ſtated to be 1451; the number of houſes, which are chiefly conſtructed of blue rag-ſtone, and covered with ſlate, was 276. A market is held on Saturdays, and two fairs annually.

Lyme was the birth-place of Thomas Coram, the benevolent patron and contriver of the Foundling hoſpital in London. He died March 19, 1751, in his eighty-fourth year, and was buried in the vault under the chapel of the hoſpital, where an inſcription perpetuates his memory. Beauties of England and Wales, vol. iv. Hutchins' Hiſtory and Antiquities of Dorſetſhire, 2 vols. folio.

LYMFIORD, or Lymfurt, a gulf of Denmark, near the weſt coaſt of North Jutland, communicating with the Cattegat, and running 80 miles inland, gradually widening, and ſeparated from the North ſea only by a narrow ſtrip of land. N. lat. 56° 39'.

LYMINGTON, a borough and market-town in the pariſh of Boldre, in the New Foreſt of Hampſhire, England, is ſituated on the declivity of a riſing ground, on the eaſtern bank of the Lymington river, about a mile from its confluence with the ſea; at the diſtance of 16 miles from Southampton, and 95 from London. It is of remote, though unknown origin: from a conſideration of local circumſtances, Mr. Warner ſuppoſes that a town or village was formed near this ſpot by the Britons. That the Romans were acquainted with it, is evinced by the contiguity of an encampment called Buckland Rings, or Caſtle Field, and by the evidence of Roman coins, nearly 200lbs. weight of which, of the Lower Empire, were diſcovered here in two urns in the year 1744. Lymington occurs in Domeſday book under the name of Lentune: but it does not ſeem to have attained any conſiderable importance till it became the property of baron de Redvers, in the time of Henry I.; when, a port being eſtabliſhed, the wines of France, and other foreign commodities, were unſhipped at its quays. It then alſo became famous for its ſalt-works; though this manufacture is, with great probability, ſuppoſed to have been eſtabliſhed at a much earlier period. A very extenſive manufacture of marine ſalt is now carried on here: the works are ſituated on the borders of the ſea-ſhore, and reach nearly three miles in a ſouth-weſt direction. The town conſiſts principally of one long ſtreet, and is divided into the *new* and *old* town by the church, which, though originally a regular pile, conſiſting of a nave, chancel, and aiſles, with a ſpire in the centre, is now, through ſucceſſive alterations, become extremely informal. The town hall is a neat building: and here are two ſets of baths, which are rendered very convenient, and are much frequented. Lymington was ſummoned as a borough to ſend repreſentatives to parliament in the reign of Edward III.: but it does not appear to have complied with this precept till the 27th of Elizabeth. In the reign of James I. it was incorporated by charter, and from that period the returns have been regular. The right of election is veſted in the mayor and burgeſſes, in number about eighty. The population was ſtated, under the act of the year 1800, to be 2378; the houſes 492. A market is held on Saturdays; and two fairs annually. The ſituation of Lymington, on the banks of a navigable river, and ſo contiguous to the ſea, is extremely favourable for trade; but this advantage was formerly much greater than at preſent, as, by the injudicious conſtruction of a cauſeway, the depth of the river has been conſiderably leſſened, and its channel contracted. Previous to the making of this cauſeway, which was about the year 1730, veſſels of upwards of 500 tons burthen could be brought up to the quay; though now one of 300 tons can ſcarcely be navigated. Beauties of England and Wales, vol. vi. Warner's Account of Lymington, 12mo.

LYMPHA, Lymph, in *Anatomy*, a term given to the tranſparent fluid conveyed in the abſorbing veſſels of the body; alſo to a part of the blood. (See Absorption and Blood.) It is often applied alſo to other animal fluids, chiefly when clear and nearly tranſparent.

LYMPHÆ Ductus, a name given ſometimes to the lymphatic veſſels.

Lymphæ, among the *Romans*, a kind of grottoes, or artificial caves, ſo called from *lympha, water*; becauſe they were furniſhed with a great many tubes, canals, and ſecret paſſages, through which the water ſuddenly guſhed upon the ſpectators, while buſy in admiring the great variety and beautiful arrangement of ſhells, with which the grotto was adorned.

LYMPHATI, or Lymphatici, in *Antiquity*, a name given by the Latins to poſſeſſed or mad perſons, becauſe they were thought to be gifted with divination. Plin. Nat. Hiſt. lib. xxv. cap. 5. p. 368. edit. Hard. See Larvati.

Theſe anſwer to the νυμφοληπτοι of the Greeks: the ancient Greeks called water *nympha*, which the Latins changed into *lympha*. The term *omphi*, ſays Mr. Bryant, is of great antiquity, and denotes an oracular influence, by which people obtained an inſight into the ſecrets of futurity: it was written *omphi* or *amphi*, and ſignified the oracle of Ham, who, according to the Egyptian theology, was the ſame as the ſun, or Oſiris: and as fountains were deemed ſacred, theſe were ſtyled by the Amonians *Ain omphe*, or the fountains of the oracle, from the divine influence with which they were ſuppoſed to abound, which terms were afterwards contracted by the Greeks into νυμφη, *a nymph*, who ſuppoſed ſuch a perſon to be an inferior goddeſs who preſided over waters. In the ſame manner from *al omphia* was derived *lympha*, which differed from aqua or common water, becauſe it was of a ſacred or prophetic nature. Analyſis of Ant. Myth. vol. i. p. 280.

LYMPHATICS, in *Anatomy*, are the abſorbing veſſels. This ſyſtem is an aſſemblage of numerous ſmall veſſels, ariſing from all parts of the body, carrying from them various fluids, which they pour into the venous ſyſtem, after making them paſs through certain ſmall bodies called lymphatic glands, and forming part of the ſame ſyſtem with them. The term lymphatics was applied to theſe tubes in conſequence of their containing, in general, a tranſparent fluid or lymph; and it deſignates, therefore, properly ſpeaking, only thoſe abſorbents, of which the contents reſemble lymph. The veſſels, which take up the chyle from the inteſtines, are called lacteals, from the appearance of their contents. As the ſtructure and offices of the organs are the ſame in all parts, theſe diſtinctions might lead to erroneous views of the ſubject; and the term abſorbents, which denotes their general function, ſeems the moſt appropriate. Names derived from the nature of the fluid abſorbed are more particularly objectionable, becauſe that is very imperfectly known to us. We cannot ſuppoſe that one and the ſame fluid is abſorbed from ſerous cavities, from the adipous cells, from muſcles, glands, bones, &c.; yet in all theſe caſes it goes under the common and very indefinite term lymph.

Like the termination of the exhalants, the origin of the abſorbents cannot be demonſtrated. They are ſo extremely delicate, that the eye, aſſiſted even by the beſt optical inſtruments, cannot diſcern them: we muſt therefore infer their exiſtence from phenomena, and conclude that abſorbing veſſels ariſe wherever abſorption takes place. An attentive examination of abſorptions ſhews us that they occur wherever there is exhalation; ſo that the ſame table may ſerve both for exhalants and abſorbents. The following one repreſents the latter.

Abſorbing veſſels.

- 1. External, ariſing on
  - 1. The mucous ſurfaces.
  - 2. The ſkin.
- 2. Internal, ariſing on
  - 1. The ſerous ſurfaces.
  - 2. The cellular ſyſtem; and deriving from it
    - 1. Serum.
    - 2. Fat.
  - 3. The medullary ſyſtem
    - 1. Of ſhort and broad bones; and the extremities of long bones.
    - 2. Of the middle of long bones.
  - 4. The ſynovial ſyſtem
    - 1. Of the joints.
    - 2. Of tendinous ſheaths.
- 3. Of nutrition, taking up the reſidual nutritive matter of each organ.

The ſtructure, properties, functions, and diſtribution of the abſorbing ſyſtems, both the veſſels and glands, are conſidered in detail in the articles ABSORBENTS and ABSORPTION.

LYMPHATICS *of Birds and Fiſhes*. See *Anatomy of* BIRDS and FISHES.

LYNCHBURG, in *Geography*, a poſt-town of Virginia, in Bedford county, on the S. ſide of James river, nearly oppoſite to Maddiſon, and one mile diſtant. It contains about 100 houſes, and a large warehouſe for the inſpection of tobacco; 12 miles from London.

LYNCHET, among *Farmers*, a line of green ſward, ſerving as a boundary to ſeparate ploughed land, in common fields. See BALKS.

LYNCHVILLE, in *Geography*, a poſt-town of Marion county, South Carolina, 450 miles from Waſhington.

LYNCIS LAPIS, in *Natural Hiſtory*, the name given by ſome of the writers of the middle age to the *belemnites*.

LYNCURIUM, or LYNCURIUS, in *Mineralogical Antiquities*, a mineral ſubſtance, reſpecting the nature of which ſeveral conjectures have been broached, from the time of Pliny down to the preſent day. The opinions of the preſent mineralogiſts appear to be divided between amber and hyacinth; but it is moſt probable that both theſe ſubſtances have been confounded under the name of lyncurium. Pliny, in ſpeaking of the mineral in queſtion, is inclined to deny its very exiſtence: "De lyncurio," he ſays "maxime dici cogit auctorum pertinacia. Quippe etiamſi electrum id eſſet, lyncurium tamen gemmam eſſe contendunt. Fieri autem ex urina quidem lyncis, ſed congeſta terra protinus beſtia aperiente eam, quoniam invideat hominum uſui. Eſſe autem qualem in igneis ſuccinis, colorem, ſcalpique. Nec folia tantum aut ſtramenta ad ſe rapere, ſed æris etiam ac ferri laminas, quod Diocles quidem et Theophraſtus credidit. *Ego falſum id totum arbitror*, nec viſam in ævo noſtro gemmam ullam ea appellatione." (Hiſt. Nat. xxxvii. 3.) It is remarkable that Pliny, whoſe incredulity upon other occaſions was certainly not over great, ſhould have treated the whole of what has been ſaid of the lyncurium as a mere fable, when his ſcepticiſm might have more properly been confined to that part of the ſtory which relates to the origin of the ſubſtance in queſtion. Inſtead of this, in ſpeaking of the lynx, he actually gives credit to what has been ſaid of the extraordinary quality of its urine. "Lyncum humor (he ſays) ita redditus ubi gignuntur glaciatur, areſcitve in gemmas, carbunculis ſimiles, et igneo colore fulgentes, lyncurium vacatas, atque ob id ſuccino a pleriſque ita generari prodito." Ib. viii. 38.

Theophraſtus, from whom Pliny has principally derived his information reſpecting lyncurium, mentions among its qualities that of attracting, like amber, particles of ſtraw, and even thin laminæ of copper or iron. Our hyacinth does not poſſeſs the quality of becoming electric by friction; a circumſtance to which ſir John Hill does not advert in his obſervations on this ſtone, which he conſiders as the only one that can be ſaid to anſwer the deſcription given of the lyncurium by Theophraſtus. On the other hand, it muſt be confeſſed that its remaining qualities, as mentioned by the Ereſian philoſopher, *viz.* the conſiderable hardneſs attributed to it, and the conſequent uſe made of it for engraving ſeals on, do not exactly ſquare with the well known characters of amber, which is moreover ſeparately deſcribed in his work as a ſubſtance perfectly diſtinct from lyncurium.

It is more than probable, that in this caſe, as in many others, the qualities of two diſtinct ſubſtances have been erroneouſly combined by the ancients, who, in their attempt to identify natural bodies, were but too often ſtrangely miſled by a fancied ſimilarity of characters, where the eye of a modern naturaliſt would ſcarcely diſcover traces of the moſt diſtant reſemblance.

It would appear that the fineſt amber, and a particular deep-coloured variety of it, was formerly obtained from Liguria, where, indeed, it ſtill occurs, though not in the ſame quantity in which it is found on the ſea-coaſt of Pruſſia. If we may ſuppoſe the word *licurium* to have been derived from that part of Italy, it is certainly equally probable that ignorance and the love of the marvellous may afterwards have ſubſtituted that of *lyncurium*, implying the fabulous origin of this ſubſtance from the urine of the lynx. Similarity of colour appears to have been ſufficient afterwards to affix the ſame appellation to the hyacinth; and it is probably this confuſion which produced the deſcription of Theophraſtus above alluded to, and which is partly applicable to amber, and partly to the hyacinth, or any other hard ſtone of ſimilar colour and tranſparency, ſuch as yellow garnets, yellow calcedony, &c.

Among the authors who have conſidered amber to be the lyncurium of the ancients, are Geoffroy, Geſner, Beckman, and Napione; moſt of the other modern writers on mineralogy follow St. Epiphanius, Leſſer, and Hill, who are decidedly of opinion that the hyacinth alone could have been meant by it. Sir William Watſon ſuppoſes that Theophraſtus's tus's deſcription is applicable to the tourmalin, the electrical phenomena of which are however of a peculiar nature ; not to mention other objections that may be urged againſt the identity of the two ſubſtances.

Of other opinions on this ſubject none deſerve to be mentioned, except, perhaps, on account of its ſingularity, that of Woodward, and ſome writers before and after him, who ſuppoſed the lyncurium to be the calcareous petrifaction known by the name of *belemnites.* Indeed it is difficult to gueſs what can have given origin to this ſtrange ſuppoſition, unleſs it be the circumſtance that theſe belemnites, when burnt, are ſaid to give out an unpleaſant urinous odour.

In the Vulgate, mention is made of the ligurius, as one of the twelve precious ſtones in the breaſt plate of the high prieſt. In the verſion of the Septuagint, it is called Λυγκούριον. St. Epiphanius, enumerating the ſame twelve gems, gives the following account of the ſtone in queſtion : "Ligurius vel lyncurius gemma ; de hujus inventione vel apud naturæ indagatores, vel apud alios veteres qui harum rerum meminerunt, nihil cognovimus. Invenimus tamen languriam gemmam vocatam, quam vulgari lingua lagurium appellant. Et forte puto hunc eſſe lygurium." (St. Epiph. Opp. latine.) The ſame writer and Hieronymus ſuſpect the lyncurium to be the hyacinth ; but how unſettled the ideas of St. Epiphanius were reſpecting the latter gem, appears from the following account he gives of it : "Hyacinthus igitur diverſas habet formas ; quo enim reperitur colore profundior, eo cæteris præſtantior eſt. Similis eſt lanæ quæ ſubpurpuraſcit aliquatenus." (l. c. pag. 110.)

LYNDEBOROUGH, in *Geography*, a townſhip of America, in Hillſborough county, New Hampſhire, about 70 miles from Portſmouth ; incorporated in 1764, and containing 976 inhabitants.

LYNDHURST, a village in the pariſh of Minſted, in the New Foreſt of Hampſhire, England, is ſituated nine miles from Southampton and 86 from London, nearly in the centre of the New Foreſt, of which it has been, from the formation of the foreſt, conſidered as a ſort of capital : and here was exerciſed the juriſdiction of the chief juſtice in eyre for this foreſt, ſo long as he continued to exerciſe it, of which there are no traces ſubſequent to the reign of Charles II. All the Foreſt courts under the verderors are ſtill held here ; as well as thoſe of attachment, &c. as the ſwanimote : the former are held on ſuch days as the preſiding judges appoint, three times in a year ; the latter on the 14th of September annually. The king's houſe, in this village, though but an indifferent reſidence, is occupied by the lord warden whenever he viſits the Foreſt. An ancient ſtirrup is preſerved here, ſaid to have been worn by William Rufus at the time he was ſhot by ſir Walter Tyrrell. The king's ſtables are very large, and were probably conſidered as magnificent when firſt erected, which appears to have been about the time of Charles II. From the hotel at Lyndhurſt, which is entirely new built, and fitted up with every convenience, is a fine view of the ſea, and of the Needle rocks at the weſt end of the Iſle of Wight. Under the population act of 1800, Lyndhurſt was returned as containing 181 houſes, inhabited by 882 perſons.

About one mile weſt of Lyndhurſt is Cuffnells, the ſeat of the right honourable George Roſe, who has been here honoured with two viſits from their majeſties and the royal family in the years 1801 and 1804. Beauties of England and Wales, vol. vi. Gilpin's Obſervations on the New Foreſt, &c. 2 vols. 8vo.

LYNDON, a townſhip in Caledonia county, Vermont, N. of St. Johnſburg, and S. of Burke and Billymead ; containing 622 inhabitants.

LYNN, Sagus of the Indians, a maritime poſt-town of America, in Eſſex county, Maſſachuſetts, on a bay, N.E. of Boſton bay, and about nine miles N. by E. from the town of Boſton. The townſhip was incorporated in 1637, and contains 2837 inhabitants. In this townſhip are two pariſhes, beſides a ſociety of Methodiſts, and a large number of Friends. The principal manufacture is that of women's ſilk and cloth ſhoes, which are ſold for home uſe, and ſhipped to the ſouthern ſtates and to the Weſt Indies. Lynn beach, which is a mile in length, connects the peninſula, called "Nahant" with the main land. In the ſummer ſeaſon it is a place of great reſort from neighbouring towns, and uſed as a race-ground.

Lynn *River*, a river of Norfolk county, in Upper Canada, which riſes in Windham townſhip, and diſcharges itſelf into lake Erie, affording a good harbour for batteaux.

Lynn *Canal*, an inlet on the W. coaſt of North America, and upper arm of Croſs ſound ; extending about 60 miles N. from the N. extremity of Chatham Sound ; ſo named by Capt. Vancouver, from Lynn, the place of his nativity. The entrance to the S. is in N. lat. 58° 12′. E. long. 225° 12′.

LYNNFIELD, a townſhip of America, in Eſſex county, Maſſachuſetts, N.E. of Salem, and 15 miles N. by E. from Boſton ; incorporated in 1782, and containing 468 inhabitants.

LYNNHAVEN Lake, a bay at the S. end of Cheſapeak bay, into which Lynnhaven river diſcharges its waters ; lying between the mouth of James's river and cape Henry.

LYNN-REGIS, or King's Lynn, a large reſpectable ſea-port, borough, and market town, in the hundred of Freebridge Lynn, in the county of Norfolk, England, is ſituated ten miles from the Britiſh ocean, on the eaſtern bank of the Great Ouſe river, which at this place is nearly the breadth of the Thames above London bridge. Lynn is diſtant from Norwich 44 miles, and from London 96. It is written Lun and Lena in Domeſday book ; and appears to have been, at the time of that ſurvey, a place of ſome conſequence and trade. Previous to the reign of Henry VIII. it was called Biſhop's Lynn, but falling into the poſſeſſion of that monarch he changed its name to Lynn Regis. The town is nearly one mile and a quarter in length ; its greateſt breadth being half a mile. Four ſmall rivers, called Fleets, divide it into ſeveral parts, which are connected by eleven bridges. The whole is encompaſſed on the land ſide by a deep wet foſs, flanked by a wall, which was formerly defended by nine baſtions, but is now in a dilapidated ſtate. At the north end is a platform battery, called St. Anne's port, mounted with ten eighteen pounders, which were planted here in 1627. Great improvements have been recently made in the ſtreets and avenues of the town.

Lynn has had fifteen charters granted to it by various ſovereigns of England. It was firſt incorporated by king John ; and has ſent two burgeſſes to parliament ever ſince the twenty-ſixth year of Edward I. The right of election is veſted in the freemen and free burgeſſes, in number about 330. The corporation conſiſts of a mayor, recorder, twelve aldermen, and eighteen common council-men. By the population ſurvey, made in the year 1800, the number of houſes was 2012, occupied by 10,096 perſons.

The town contains ſeveral public buildings, ſome of which exhibit curious ſpecimens of architectural antiquity. The principal is the church of St. Margaret, which, with a priory, was founded by Herbert, biſhop of Norwich, in the time of William Rufus. It was a very ſpacious ſtructure, and though now curtailed of its original dimenſion is ſtill a large and noble pile. It conſiſts of a nave with aiſles, a chancel or choir with aiſles, a tranſept, and two towers at the weſt end; the roof is ſupported by twenty-two columns, which ſeparate the body from the aiſles. At the eaſtern extremity of the town is an ancient edifice, called the Lady's or the Red Mount chapel; which conſiſts of an octagonal wall of red brick, and is conſtructed on a very ſingular plan. Within this is a handſome cruciform chapel, ſeventeen feet in length, fourteen in breadth, and thirteen in height; the roof is formed of ſtone, with numerous groins, &c. exactly reſembling the ceiling of King's college chapel, Cambridge. This curious ſtructure is verging to decay. St. Nicholas's chapel, built about the time of Edward III., is 200 feet in length, 78 in breadth, and 170 feet from the foundation to the top of the tower. The body conſiſts of a nave ſeparated from the aiſles by ten ſlender columns on each ſide, ſupporting an equal number of acutely pointed arches: the roof is groined, and the entrance doors are finely carved. A large monument of white marble commemorates ſir Benjamin Keene, K.B. a native of this town, and many years ambaſſador to the court of Madrid, in which city he died, Dec. 15, 1757; his remains were brought here for interment. The eaſt and weſt windows of this chapel are large, and are both adorned with numerous mullions and tracery. The ſouthern porch is profuſely ornamented with tracery, niches, &c. A view and plan of this porch, with plan, views, ſection, &c. of the Red Mount chapel, alſo hiſtorical and deſcriptive accounts of the two buildings, are publiſhed in Britton's Architectural Antiquities of Great Britain, vol. iii.

The chapel of St. James, after the diſſolution, being in a ruinous condition, was rebuilt in 1682, and converted into an hoſpital for fifty poor people. Great additions have ſince been made to the building, and it is now the general workhouſe for the town. The Exchange, or Cuſtom houſe, which was erected in 1683 by ſir John Turner, knt. is a neat freeſtone building, with two tiers of pilaſters, the lower in the Doric, and the upper in the Ionic order; it occupies the ſcite of an old religious houſe, which was appropriated to the Trinity guild. Several other religious eſtabliſhments were founded here, of which few veſtiges remain, except an hexagonal ſteeple, belonging to the monaſtery of the Grey friars, which ſerves as a good land-mark to veſſels entering the harbour. Two markets are held on Tueſdays and Saturdays, in different places: the Tueſday market-place compriſes an area of three acres, ſurrounded by ſome good houſes; near the centre, on an aſcent of four ſteps, ſtands a building, called the Market-croſs, of freeſtone, erected in the year 1710; the lower part is encompaſſed by a periſtyle formed by ſixteen Ionic columns; the upper part is finiſhed with a cupola, and the whole is ſeventy feet in height. The Saturday market is kept in a convenient area recently opened near St. Margaret's church-yard. The Guildhall is an ancient ſtructure of ſtone and flint; it contains a large ſtone hall, courts for the adminiſtration of juſtice, and three ſpacious aſſembly rooms. On the firſt Monday in every month, the mayor, aldermen, magiſtrates and clergymen meet, to hear and determine all controverſies between the inhabitants, in an amicable manner, for the prevention of law-ſuits. This laudable practice originated in the year 1558, and is called the Feaſt of Reconciliation. This town, not having any freſh ſprings, was formerly much diſtreſſed for water; but it is now ſupplied from a river near Gaywood, whence the water is conveyed by ſmall canals, to the conduits in the town.

Lynn harbour is deep, but the anchorage is bad, from the oozy bed of the river. It is capable of receiving three hundred ſail of ſhipping. At what time it was firſt uſed as a haven is not aſcertained: but ſubſequent to the reign of Henry III. Lynn aſpired to commercial conſequence, gradually roſe from its primitive obſcurity, and progreſſively became a conſiderable port. Its ſituation, ſo near the North ſea, and the inland navigation connected with it, gives the town great commercial advantages. It is open to a communication with all the north of Europe; and, by means of the Ouſe and its collateral rivers, can extend its navigation into eight counties, excluſive of other conveyances by land carriage and canals. It imports annually about 100,000 chaldrons of coals, and above 2000 pipes of wine; in which two articles it exceeds all other ports in England, except London, Briſtol, and Newcaſtle. In return for theſe, and other heavy articles, with which it ſupplies the interior, it receives back for exportation corn and various manufactured articles. Beauties of England and Wales, vol. xi. Richards's Hiſtory, &c. of King's Lynn, 8vo. 1811. Parkin's Hiſtory of Lynn, folio.

LYNX, in *Aſtronomy*, is a conſtellation of the northern hemiſphere, made by Hevelius out of unformed ſtars: the number of ſtars in Hevelius's catalogue is nineteen, and in the Britannic is forty-four. See CONSTELLATION.

LYNX, in *Mythology*, was a fabulous animal conſecrated to Bacchus. See FELIS *Lynx*.

LYNX, in *Zoology*. See FELIS *Lynx*.

LYNX, *Perſian*. See FELIS *Caracal*.

LYOE, in *Geography*, a ſmall iſland of Denmark, near the S. coaſt of Funen. N. lat. 55 3′. E. long. 10° 10′.

LYOENA, a town of Africa, in the kingdom of Algiers, where the independent Arabs lodge their riches as in a place of ſafety; as it is defended by a warlike tribe, who have withſtood the power of the Turks; 106 miles S. of Conſtantina.

LYON, a river of Scotland, which riſes in Loch Lyon, on the S.W. part of the county of Perth, and runs into the Tay; 2 miles E.N.E. of Kenmore.

LYONNET, PETER, in *Biography*, an eminent naturaliſt, was born at Maeſtricht in 1707. He acquired a good knowledge of modern and ancient languages, underſtood muſic, and was a good engraver and ſculptor. He had been originally bred to the law, and became ſecretary to the ſtates of Holland. In the latter years of his life he applied the whole force of his mind to the ſtudy of natural hiſtory, particularly to the ſcience of entomology, on which he wrote ſeveral books. He died at the Hague in 1789: he had been elected a member of the Royal Society of London, and of ſeveral foreign academies.

LYONNOIS, in *Geography*, *Pagus Lugdunenſis*, was, before the revolution, a province of France, bounded on the N. by Bourgogne and Maconnois, on the E. by the Saône and the Rhone, on the S. by Languedoc, and on the W. by Auvergne; lying between 45° 15′ and 46° 15′ N. lat. and between 3° 45′ and 4° 50′ E. long.; being 24 leagues from N. to S. and 16 from W. to E. This province is watered by the Rhone, the Saône, and the Loire, and is moderately fertile, producing grain, wine, and fruits. It was annexed to the crown of France in 1563; and conſiſted of three ſmall provinces, *viz.* Lyonnois Proper, Forez, and Beaujolais. The former, being thirteen leagues in length, and eight in breadth, is diverſified with hills, gentle eminences, and plains. It yields little grain; but ſome diſtricts furniſh good wine, and excellent paſturage. It has a copper mine, and a mineral ſpring. Forez conſiſts principally of an extenſive and fruitful valley, yielding grain, wine, hemp, and cheſnuts, and is watered by the Loire and other ſtreams. Beaujolais is a fertile diſtrict, twelve leagues in length, and ſeven in breadth. Lyonnois and Beaujolais are now included in the department of the Rhone and Forez in that of the Loire.

LYONS, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, near the E. coaſt of Oby. S. lat. 1° 35′. E. long. 128° 14′.

Lyons, *Lugdunum*, a city of France, and capital of the department of the Rhone; but, before the revolution, the capital of the province called Lyonnois, above deſcribed, ſituated at the conflux of the Rhône and the Saône; over the former there are two bridges, and over the latter three. This city was one of the places conquered by Cæſar; but a little after the death of this dictator, Munatius Plancus received orders from the Roman ſenate to re-aſſemble at Lugdunum the inhabitants of Vienne, who had been driven from this city by the Allobroges. In a little time this colony became very powerful, ſo that Strabo ſays it was not inferior to Narbonne, with reſpect to number of inhabitants. In the fifth century this city was taken by the Burgundians, whoſe king became feudatory to Clovis. The ſons of Clovis, however, ſubdued the Burgundians, and took poſſeſſion of Lyons. When the dominions of Lewis Debonnaire were divided, Lyons, with the greateſt part of Burgundy, was transferred to Lothaire. Before the revolution, it was the ſee of an archbiſhop, who was primate of France, and was reckoned the ſecond city of the kingdom in trade, manufactures, and commerce; and was ſuppoſed to contain 150,000 inhabitants. Theſe were, in all periods, diſtinguiſhed for induſtry, arts, and love of freedom. Under the Romans, as a municipium, it poſſeſſed valuable immunities: and when it became a colony, it was cheriſhed and protected. Under the ſovereigns of France, it has enjoyed peculiar privileges, being governed by its own magiſtrates, and guarded by its own militia. Four annual fairs, each of fifteen days, inſtituted in the reign of Lewis XI., have much contributed to the advancement of its traffic. Its good government naturally attracted citizens, whilſt the troubles excited at various periods in the neighbouring ſtates, more eſpecially about the year 1290, between the contending factions of the Guelphs and Ghibellines, occaſioned many from Italy and Florence to take refuge in a city where they could live in ſecurity and peace. The principal dependence of Lyons, and the ſource of its wealth, have been its manufacture of ſilk in all its branches. The trade of Lyons has been immenſe with Spain, Italy, Switzerland, Germany, Holland, England, &c. From Spain, the inhabitants received wool, ſilks, drugs, piaſtres, and ingots of gold and ſilver, in return for cloth, linen, fuſtian, coffee, paper, &c. To Italy they ſent cloth, linen, ſilk ſtuffs, lace, books, mercery, and millinery, receiving in return ſilk, velvet, damaſk, ſatin, taffeties, and rice. To Switzerland they ſent coarſe cloth, hats, ſaffron, wine, oil, ſoap, and mercery, and received from thence cheeſe, linen, and, in time of war, horſes. The great towns of Germany purchaſe from Lyons, beſides the ſame merchandize as the Swiſs, ſtuffs of gold and ſilver. From Holland, Lyons took more merchandize than that which it ſent in return. With the other parts of France it carried on a very conſiderable trade. Lyons reckoned eleven pariſhes, ſix gates, four fauxbourgs, and was divided into thirty-five diſtricts, named "Panonages." The cathedral church was a magnificent Gothic building; the town-houſe is eſteemed one of the moſt beautiful in Europe; and its other public buildings, before the revolution, were four abbies, fifty convents, three public ſchools, a college of phyſic, two general hoſpitals, &c.; and, beſides theſe, an academy of ſciences, inſtituted A. D. 1700, and an academy of fine arts, eſtabliſhed in 1724, both which were united in 1758, a ſociety of agriculture, a veterinary ſchool, a theatre, a public library, ſeventy companies of tradeſmen and artiſts, three forts, an arſenal well ſupplied and carefully arranged, an infirmary, five hundred feet in length, &c. to all which we may add magnificent quays. At an early period of the revolution, an union was formed between the towns of Lyons, Marſeilles and Toulon, under the title of "Federal Republicaniſm," contrary to the ſenſe of the nation, which inclined to favour a republic one and indiviſible. Lyons contained a great number of diſaffected perſons, both Royaliſts and Girondiſts, and was declared to be in a ſtate of rebellion. After a ſiege of two months, during which it is ſuppoſed to have loſt 2000 men, and a great part of the city was reduced to aſhes, Lyons ſurrendered, and many of the rebels who were not able to eſcape were taken and executed. By a decree of the convention, the walls and public buildings of Lyons were ordered to be deſtroyed, and the name of the city itſelf to be changed into that of "Ville Affranchie;" but this decree was afterwards repealed. It is ſtated to contain 109,500 inhabitants, and the ſix cantons, into which it is divided, to include 123,510, on a territory of 55 kiliometres, in four communes. N. lat. 45° 46′. E. long. 4° 50′.

Lyons, a village of America, in Ontario county, and townſhip of Phelps, in New York, at the junction of Mud and Canandarque creeks; 16 miles N. of Geneva, and about 20 S. of Sodus; ſituated in a fine country, and accommodated with excellent advantages for water-conveyance.

LYONSIA, in *Botany*, ſerves to commemorate Mr. Iſrael Lyons, born at Cambridge in 1739, being the ſon of a Poliſh Jew, ſettled there as a ſilverſmith; who publiſhed "A Hebrew Grammar," and "Obſervations and Enquiries relating to various Parts of Scripture Hiſtory." He was diſtinguiſhed as a mathematician and botaniſt, and had the honour of inſtructing in the latter ſcience the celebrated ſir Joſeph Banks, by whoſe recommendation he read a courſe of lectures on Botany at Oxford, where ſuch a courſe was then much wanted. He died in London of the meaſles, about two years after he had accompanied Captain Phipps, afterwards lord Mulgrave, towards the north pole, in 1773. For ſome time he was employed as one of the calculators of the Nautical Almanac, for which he received an annual ſalary of an hundred pounds: and at the time of his death he was preparing for the preſs a complete edition of all the works of Dr. Halley. Beſides ſeveral mathematical works, among which we may reckon his "Fluxions," publiſhed in 1758; he had in contemplation a *Flora Cantabrigenſis;* but publiſhed only a "*Faſciculus*" of plants diſcovered in that neighbourhood ſince the time of Ray, in 1763, in 8vo. Brown. Prodr. Nov. Holl. v. 1. 466. Wern. Tranſ. v. 1. 66.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. Brown.

Eſſ. Ch. Corolla funnel-ſhaped; its mouth and tube without ſcales; limb in five deep, recurved, equilateral ſegments. Stamens prominent; filaments thread-ſhaped, inſerted into the middle of the tube; anthers arrow-ſhaped, cohering with the ſtigma by the middle, their hind lobes void of pollen. Germen of two cells; ſtyle one, thread-ſhaped, dilated at the top; ſtigma ſomewhat conical. Scales at the baſe of the germen combined. Capſule cylindrical, of two cells, its valves like follicles, with a parallel diſtinct partition, bearing the ſeeds on each ſide upon fixed receptacles.

1. L. *ſtraminea*, the only ſpecies, gathered by Mr. Brown

at Port Jackſon, and in Van Diemen's land. A climbing *ſhrub*, with oppoſite *leaves*. *Cymes* terminal, three forked. *Flowers* among the ſmalleſt of this tribe, their limbs bearded.

LYPERANTHUS, from λυπη, *ſadneſs*, and ανθος, a *flower*, becauſe of the very dark-red gloomy hue of the bloſſoms, which is unuſual in this tribe.—Brown Prodr. Nov. Holl. v. 1. 325.—Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth ſuperior, ringent, of three leaves, the upper one vaulted, the reſt flattiſh. *Cor.* Petals two, nearly equal and ſimilar to the flatter calyx-leaves. Nectary ſhorter, its edges aſcending, hood-like, with a taper point, the diſk glandular or papillary. *Stam.* Anther terminal, permanent, its cells cloſe together; maſſes of pollen two in each cell, powdery. *Piſt.* Germen inferior; ſtyle columnar, linear. *Peric.* Capſule. *Seeds* numerous.

Eſſ. Ch. Calyx ringent; its upper leaf vaulted. Lip ſhorter, hooded, glandular, with a taper point. Style linear. Anther vertical, permanent.

A genus of ſmooth *Orchideæ*, growing on the ground. Bulbs naked, undivided, terminating the deſcending caudex, which throws out roots above them. Stem bearing a ſingle leaf cloſe to the root, and two bracteas above, beſides what accompany each flower. Flowers racemoſe, very dark red, moſtly reverſed.

1. L. *ſuaveolens*. Leaf linear, elongated. Petals aſcending. Diſk of the nectary bearing rows of ſeſſile glands; its margin naked.—Found near Port Jackſon, New South Wales.

2. L. *ellipticus*. Leaf lanceolate-elliptical. Diſk of the nectary papillary; its margin naked.—Gathered by Mr. G. Caley in the ſame neighbourhood.

3. L. *nigricans*. Leaf ovate, ſomewhat heart-ſhaped. Petals divided. Lip fringed; its diſk papillary.—Found by Mr. Brown near Port Jackſon, as well as in the ſouthern part of New Holland.

LYRA, in *Anatomy*, a name applied to a certain part of the brain. See Brain.

Lyra, in *Aſtronomy*, a conſtellation in the northern hemiſphere.

The number of its ſtars, in Ptolemy's catalogue, is ten; in Tycho's, eleven; in Hevelius's, ſeventeen; and in the Britannic catalogue, twenty-one. See Constellation.

Lyra, Nicholas de, in *Biography*, a learned French monk and commentator on the ſcriptures in the thirteenth and fourteenth centuries, was born in a ſmall town in the dioceſe of Evreux, in Normandy. He was deſcended from Jewiſh parents, but becoming a Chriſtian, he embraced a religious life in a monaſtery at Verneuil, in 1291. Having remained there ſome time, he was ſent to Paris, where he applied with the greateſt diligence to his ſtudies, and was admitted to the degree of doctor. He died in this city in the year 1340. He was author of "Poſtills," or a compendium of the whole bible, which he began in 1293, and finiſhed in the year 1330. The firſt edition of this work was publiſhed at Rome in 1472, in ſeven volumes folio, and is now become rare; but it has ſince undergone various impreſſions at Baſil, Lyons, Doway, Antwerp, &c. of which the beſt is ſaid to be that of Antwerp in 1634, in ſix volumes folio. De Lyra was alſo the author of "Moral Commentaries upon the Scriptures;" "A Diſputation againſt the Jews;" and other pieces. Moreri.

Lyra, in *Ichthyology*, the name of a fiſh of the *trigla* kind, of which there are two varieties, reckoned by Artedi and Linnæus two different ſpecies. The one is the *piper* (ſee Trigla *Lyra*), the other, the *lyra cornuta*, or horned harp-fiſh. This laſt is a fiſh of an octangular form, covered all over with bony ſcales; theſe are of a rhomboidal figure, and each has in its middle a ſharp and ſtrong prickle bending backwards: it is of a red colour, and its head is very large; its ſnout divides towards the extremity into two long horns, on which are placed two perpendicular ſpines, and a third above makes an acute angle with theſe; it has one very long fin on the back, and another anſwering to it behind the anus: alſo two large ones at the gills, and two ſmaller on the belly; it has only two filaments, called fingers, behind its gill-fins; its mouth is large, but has no teeth, and there are ſeveral beards on its under jaw; two of which are longer than the reſt, and are branched: it is caught in the Mediterranean, and brought to market at Rome; it is a ſcarce fiſh in other places, and at Montpellier was once ſhewn to Mr. Ray for the remora. See Trigla *Cataphracta*.

Lyra is alſo a ſpecies of *Callionymus*; which ſee. See Dragonet, under which article the other ſpecies of the callionymus are deſcribed.

Lyra is alſo the name of a beautiful ſea-ſhell of the genus of the concha globoſa, or dolium. There are three ſpecies of the lyra, or harp-ſhell. 1. The common lyra, which has thirteen roſe-coloured ribs running along its body. 2. The eleven-ribbed lyra; and 3. The noble harp, or *lyra nobilis*. This is a moſt elegantly variegated ſhell; its ground colour is a deep brown, and its variegations very elegant and black. See Conchology.

Lyræ *Lucida*. See Lucida.

LYRATUM Folium, in *Botany*. See Leaf.

LYRE, Λυρα, *Lyra*, in the *Ancient Muſic*, a muſical inſtrument of the ſtring kind, ſo dear to the Greeks, that they have by turns attributed its invention to Mercury, Apollo, Linus, Orpheus, and Amphion; making it the ſymbol of all excellence in poetry and muſic. The poets and hiſtorians of fabulous times, however, ſeem moſt to agree in aſcribing the invention to Mercury. And among the accounts of the ſeveral writers of antiquity who have mentioned this circumſtance, and confined the invention to the Egyptian Mercury, that of Apollodorus (Bibliotheca, lib. ii.) ſeems the moſt intelligible and probable. "The Nile," ſays this writer, "after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on the ſhore a great number of dead animals of various kinds, and, among the reſt, a tortoiſe, the fleſh of which being dried and waſted by the ſun, nothing was left within the ſhell but nerves and cartilages, and theſe being braced and contracted by deſiccation, were rendered ſonorous; Mercury, in walking along the banks of the Nile, happening to ſtrike his foot againſt the ſhell of this tortoiſe, was ſo pleaſed with the ſound it produced, that it ſuggeſted to him the firſt idea of a lyre, which he afterwards conſtructed in the form of a tortoiſe, and ſtrung it with the dried ſinews of dead animals."

Cenſorinus, however (De Die Nat. cap. 22.), attributes to Apollo the firſt idea of producing ſound from a ſtring, which was ſuggeſted to him by the twang of his ſiſter Diana's bow. Ψαλλειν is ſtrictly to twang a ſtring, and Ψαλμος the ſound which the bow-ſtring produces at the emiſſion of the arrow. Euripides in Bacch. v. 782. uſes it in that ſenſe,

"——————— τοξων χερι
Ψαλλουσι νευρας."

"Who twang the nerve of each elaſtic bow."

Father Montfaucon ſays it is very difficult to determine in what the lyre, cithara, chelys, pſaltery, and harp differed from each other; as he had examined the repreſentations of ſix hundred lyres and citharas in ancient ſculpture, all which be found without a neck, and the ſtrings open as in the modern harp, played by the fingers. (Antiq. Expl. tom. iii. lib. 5. cap. 3.) But though ancient and modern authors uſually confound theſe inſtruments, yet a manifeſt diſtinction is made by Ariſt. Quintil. in the following paſſage, p. 101. After diſcuſſing the characters of wind-inſtruments, he ſays, "Among the ſtringed inſtruments, you will find the lyre of a character analogous to *maſculine,* from the great depth or gravity, and roughneſs of its tones; the ſambuca of a *feminine* character, *weak* and *delicate,* and from its great *acuteneſs,* and the ſmallneſs of its ſtrings, tending to *diſſolve* and *enervate.* Of the intermediate inſtruments, the polypthongum *partakes* moſt of the *feminine;* but the cithara *differs not much* from the *maſculine character* of the lyre." Here is a ſcale of ſtringed inſtruments; the lyre and ſambuca at the extremes; the polypthongum and cithara between; the one next to the ſambuca, the other next to the lyre. He afterwards juſt mentions that there were others between theſe. Now it is natural to infer, that as he conſtantly attributes the manly character to gravity of tone, the cithara was probably the more acute inſtrument of the two; leſs loud and *rough,* and ſtrung with ſmaller ſtrings. Concerning what difference there might be in the form and ſtructure of the inſtruments, he is wholly ſilent. The paſſage, however, is curious as far as it goes, and deciſive. The cithara may, perhaps, have been as different from the lyre, as a ſingle harp from one that is double; and it ſeems to be clearly pointed out by this multiplicity of names that the Greeks had *two* principal ſpecies of ſtringed inſtruments; one, like our harp, of full compaſs, that reſted on its baſe; the other more portable, and ſlung over the ſhoulder, like our ſmaller harp or guitar, or like the ancient lyres repreſented in ſculpture.

Tacitus, Annal. xvi. 4. among the rules of decorum obſerved by public performers, to which Nero, he ſays, ſtrictly ſubmitted, mentions, "That he was not to ſit down when tired." Ne feſſus reſideret. It is remarkable that he calls theſe rules, *Citharæ Leges,* "The Laws of the Cithara;" which ſeems to afford a pretty fair proof of its being of ſuch a ſize and form as to admit of being played on *ſtanding.*

The uſe of the phorminx in Homer, leads rather to the rough, manly, harp-like character. But a paſſage in Orpheus, Argon. 380, ſeems to make phorminx the ſame as chelys, the lutiform inſtrument of Mercury. It is there ſaid of Chiron, that he "ſometimes ſtrikes the cithara of Apollo; ſometimes the ſhell-reſounding phorminx of Mercury,

> "Αλλοτε δ’ αυ Φοιβῳ κιθαρην μετα χερσιν αρασσων,
> Ηλιγυρην φορμιγγα χελυκλονον Ερμαωνος."

This paſſage is curious; for though the Argonautics were not written by Orpheus himſelf, they have all the appearance of great antiquity.

The belly of a theorbo, or arch-lute, is uſually made in the ſhell-form, as if the idea of its origin had never been loſt; and the etymology of the word guitar ſeems naturally deducible from cithara; it is ſuppoſed that the Roman C was hard, like the modern K, and the Italian word *chitarra* is manifeſtly derived from Κιθαρα, *cithara.*

In the hymn to Mercury, aſcribed to Homer, Mercury and Apollo are ſaid to play with the cithara *under their arms,* ver. 507. ὁ δ’ ὑπωλενιον κιθαριζεν, *ſub ulna citharâ-ludebat,* "played with the cithara *under his arm.*" So in ver. 432. ἐπωλενιον, *at* his arm, ſhould, according to the critics, be ὑπωλενιον, as it is afterwards. This ſeems to point out a guitar more than a harp; but the ancients had lyres, citharas, and teſtudos of as different ſhapes from each other, as our harp, ſpinnet, virginal, and pianoforte.

Theſe paſſages in old authors are a kind of antique drawings, far more ſatisfactory than thoſe of ancient ſculpture; for we have ſeen the ſyrinx, which had a regular ſeries of notes aſcending or deſcending, repreſented with ſeven pipes, four of one length, and three of another, which of courſe would furniſh no more than two different ſounds. The cymbals too, which were to be ſtruck againſt each other, are placed in the hands of ſome antique figures in ſuch a manner, that it is impoſſible to bring them in contact with the neceſſary degree of force, without amputating, or at leaſt violently bruiſing the thumbs of the performer. And it is certain that artiſts continued to figure inſtruments in the moſt ſimple and convenient form for their deſigns, long after they had been enlarged, improved, and rendered more complicated. An inſtance of this in our own country will confirm the aſſertion. In the reign of George II. a marble ſtatue was erected to Handel, in Vauxhall gardens. The muſician is repreſented playing upon a lyre. Now if this ſtatue ſhould be preſerved from the ravages of time and accident 12 or 1400 years, the antiquaries will naturally conclude that the inſtrument upon which Handel acquired his reputation was the lyre; though we are at preſent certain that he never played on, or even ſaw a lyre, except in wood or ſtone.

In one of the ancient paintings at Portici, we ſaw a lyre with a pipe or flute for the croſs bar, or bridge at the top. Whether this tube was uſed as a flute to accompany the lyre, or only a pitch-pipe, we know not; nor in the courſe of our enquiries has any ſimilar example of ſuch a junction occurred elſewhere.

Broſſard ſeems to have abridged the hiſtory and progreſs of the lyre chronologically in the moſt ſhort and clear manner, which Graſſineau has ſpun out to great length by jumping from one century to another, and crowding together all the wild and incoherent ſtories relative to the lyre, its inventors and performers, that he could find. All that the diligent and generally accurate Broſſard ſays on the ſubject is, that the lyre was a ſtringed inſtrument, upon which the whole muſical ſyſtem of the ancients has been built. It is pretended that Mercury firſt invented it by chance, and that it had only then three ſtrings, which conſiſted of B C D; that Apollo added a fourth, Corebus, a fifth, Hyagnis, a ſixth, and Terpander, a ſeventh. It remained in this ſtate till the time of Pythagoras, or, according to others, Lycaon added to it an eighth ſtring, to render the extremities *conſonant.* Timotheus afterwards added a ninth, tenth, and eleventh ſtring. Others after him increaſed the number to ſixteen, that is, fifteen principals, and one added, which will be explained in the articles PROSLAMBANOMINOS and SYSTEM; which ſee.

Mr. Barnes, in the prolegomena to his edition of Anacreon, has an inquiry into the antiquity and ſtructure of the lyre; of which he makes Jubal the firſt inventor. For the ſeveral changes this inſtrument underwent, by the addition of new ſtrings, he obſerves, that, according to Diodorus, it had originally only three, referring to the three ſeaſons of the year, as the Greeks counted them, *viz.* ſpring, ſummer, and autumn; whence it was called τριχορδος. Afterwards it had ſeven ſtrings; as appears from Homer, Pindar, Horace, Virgil, &c. Feſtus Avienus gives the lyre of Orpheus nine ſtrings. David mentions an inſtrument of that ſort ſtrung with ten, *in pſalterio decachordo.* Timotheus of Miletus added four to the old ſeven, which made eleven. Joſephus, in his Jewiſh Antiquities, makes mention of one with twelve ſtrings; to which were afterwards added ſix others, which made eighteen in all. Anacreon himſelf ſays, p. 253, of Mr. Barnes's edition, *canto viginti totis chordis*. As for the modern lyre, or Welſh harp, it is ſufficiently known. (See Harp.) From the lyre, which all agree to be the firſt inſtrument of the ſtringed kind in Greece, there aroſe an infinite number of others, different in ſhape and number of ſtrings; as the pſalterium, trigon, ſambucus, pectis, magadis, barbiton, teſtudo (the two laſt uſed promiſcuouſly, by Horace, with the lyre and cithara), epigonium, ſimmicium, and pandura; which were all ſtruck with the hand, or a plectrum. See Psaltery, Sambuca, Magadis, Barbiton, and Cithara.

Lyre, *Lydian*. See Lydian *Lyre*.

Lyre *of the Muſcovites*. This is a rude and coarſe inſtrument, in the form of the ancient lyre of ſix ſtrings, as thick as packthread, which are thrummed with the naked fingers after the manner of the lute.

Lyre, among painters, ſtatuaries, &c. is an attribute of Apollo and the Muſes.

LYRIC, ſomething ſung or played on the lyre or harp.

Lyric is more particularly applied to the ancient odes and ſtanzas; which anſwer to our airs or ſongs, and may be played on inſtruments. See the next article.

Lyric *Poetry*, verſes written for muſic; which, with the ancients, implied verſes to be ſung to the accompaniment of the lyre. In the ſupplement to the firſt edition of the folio Encyclopédie, there is a very long article on the ſubject. We have often admired the ingenuity, refinement, and apparent feeling, with which the French treat the ſubject of dramatic muſic. Even in the feuds and diſcuſſions of the Gluckiſts and Picciniſts, many of the tracts and pamphlets ſeem to breathe the pureſt taſte and moſt profound reaſoning of which the theme is capable. The Italians, who have ſo long furniſhed models of perfection to the reſt of Europe in compoſition and performance, have not half ſo much to ſay in defence of their talents as the French in attacking them.

The article Lyric Poetry in the ſupplement to the firſt edition of the Encyclopédie, written long before the firm adherents to Lulli and Rameau were extinct, is of great length, and ſeems to flow from a writer who had read, meditated, and felt, with enthuſiaſm, all the inſpirations of the lyric bards of Greece. He has taken a wide range in treating the ſubject, and conſidered the union of poetry and muſic, not only with more enlarged views than any other modern, but perhaps than the ancients themſelves. He begins in the following manner: "The lyric poetry of the Grecians was not only ſung, but compoſed to the chords of the lyre. This was at firſt the characteriſtic diſtinction of all that was called lyric poetry by the Romans, and their deſcendants and imitators in later times. The poet was a muſician, he called upon the god of verſe, and animated himſelf with a prelude. He fixed upon the time, the movement, and the muſical period; the melody gave birth to the verſe; and thence was derived the unity of rhythm, character, and expreſſion, between the muſic and the poem that was ſung. Thus the poetry became naturally ſubſervient to number and cadence, and thus each lyric poet invented not only the proper kind of verſe, but alſo the ſtrophe analogous to the melody which he himſelf had created, and to which he compoſed it.

"In this reſpect, the lyric poem or ode with the Latins and with modern nations, has been nothing more than a frivolous imitation of the lyric poem of the Greeks: they ſay, *I ſing*, but never do ſing; they ſpeak of the chords of the lyre, but have never ſeen a lyre. No poet, ſince Horace incluſively, appears to have modelled his odes upon a melody. Horace adopting, by turns, the different formulæ of the Greek poets, ſeems ſo much to have forgotten that an ode ought to be ſung, that he has often ſuſpended the ſenſe at the end of the ſtrophe, where the air ought to repoſe, to the beginning of the next ſtanza."

This ſpecies of poetry was originally employed in celebrating the praiſes of gods and heroes; though it was afterwards introduced into feaſts and public diverſions: it is a miſtake to imagine Anacreon, as the Greeks do, the author of it; ſince it appears from ſcripture to have been in uſe above a thouſand years before that poet. Mr. Barnes ſhews how unjuſt it is to exclude heroic ſubjects and actions from this ſort of verſe, lyric poetry being capable of all the elevation and ſublimity ſuch ſubjects require; which he confirms by the examples of Alcæus, Steſichorus, Anacreon, and Horace, and by his own eſſay, a triumphal ode inſcribed to the duke of Marlborough, at the head of this edition: he concludes with the hiſtory of lyric poetry, and of thoſe ancients who excelled in it.

The characteriſtic of lyric poetry, which diſtinguiſhes it from all others, is *dignity* and *ſweetneſs*. As *gravity* rules in heroic verſe; *ſimplicity*, in paſtoral; *tenderneſs* and *ſoftneſs*, in elegy; *ſharpneſs* and *poignancy*, in ſatire; *mirth*, in comedy; the *pathetic*, in tragedy; and the *point*, in epigram; ſo in the lyric, the poet applies himſelf wholly to ſoothe the minds of men, by the ſweetneſs and variety of the verſe, and the delicacy and elevation of the words and thoughts; the agreeableneſs of the numbers, and the deſcription of things moſt pleaſing in their own nature. See Ode and Poetry.

LYRODI, among the *Ancients*, a kind of muſicians who played on the lyre, and ſung at the ſame time.

Lyrodi was alſo an appellation given to ſuch as made it their employment to ſing lyric poems, compoſed by others.

LYS, in *Geography*, one of the 13 departments of the region of France, called the Reunited Country, formed of a part of Auſtrian Flanders; bounded on the N. by the ſea, and on the E. by the department of the Eſcaut, in N. lat. 51°. It contains 3662½ kiliometres, or 159 ſquare leagues, and 470,707 inhabitants. It is divided into four circles or diſtricts, 36 cantons, and 250 communes. Its circles are Bruges, containing 149,421 inhabitants, Furnes, 49,808, Ypres, 107,103, and Courtray, 164,375. The annual contributions amount to 4,915,251 fr. and the annual expences for government, the adminiſtration of juſtice, and public inſtruction, amount annually to 358,916 fr. 66 cents. The capital of this department is Bruges. The ſoil, in general, is fertile, and produces all ſorts of grain, flax, tobacco, and excellent paſtures.

Lys, *St.*, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the diſtrict of Muret; 7 miles W. of Muret. The place contains 1140, and the canton 5249 inhabitants, on a territory of 190 kiliometres, in 11 communes.

LYSANDER, a townſhip of America, in Onondago county, New York, incorporated in 1794, and comprehending the military towns of Hannibal and Cicero. The number of inhabitants is 121. It is diſtant 16 miles S.E. of lake Ontario.

Lysander, in *Biography*, an eminent Spartan commander in the laſt years of the Peloponneſian war, was the ſon of Ariſtoclitus, a deſcendant of the Heraclidæ, but not of the royal line. About the year 406 B.C. Lyſander was made the naval commander of the Lacedæmonians. His firſt meaſure was to draw off Epheſus from the intereſt of Athens, which he accompliſhed, and at the ſame time gained the friendſhip of Cyrus the younger. He gave battle to the Athenian fleet, conſiſting of 120 ſhips, at

Ægos-Potamos, in the Thracian Cherſoneſus, and wholly deſtroyed it except three ſhips, with which the enemy's general fled to Evagoras, king of Cyprus. In this celebrated battle, which happened 405 years before the Chriſtian era, the Athenians loſt 3000 men, and with them their empire and influence among the neighbouring ſtates. Lyſander knew how to take advantage of this victory, and in the following year Athens, worn out by a long war of 27 years, gave itſelf up to the power of the enemy, and ſubmitted, in every reſpect, to the power of Lacedæmon. The government of Athens was totally changed, and 30 tyrants were ſet over it by Lyſander. This ſucceſs, and the honour of having put an end to the Peloponneſian war, rendered the conqueror extremely proud, and ambitious of higher diſtinctions than the conſtitution of his country would allow. He aimed at univerſal power, by eſtabliſhing ariſtocracy in the Grecian cities of Aſia, and he attempted to make the crown of Sparta elective, in order that he might ſeize it for himſelf, but was, in this reſpect, unſucceſsful, and he was accuſed of groſs corruption in endeavouring to accompliſh his purpoſes. The ſudden declaration of war againſt the Thebans ſaved him from the accuſations of his adverſaries, and he was ſent with Pauſanias againſt the enemy. The Spartan troops were defeated, and their general Lyſander killed in the year B.C. 394. His body was recovered by his colleague Pauſanias, and honoured with a magnificent funeral. Lyſander was a brave man, but his ambition merited the ſevereſt cenſure. He was arrogant and vain in his public, as well as in his private conduct, and he received and heard with the greateſt avidity the hymns which his courtiers and flatterers ſung to his honour. But in the midſt of all his pomp, his ambition, and his intrigues, he died extremely poor, and on account of his poverty his daughters were rejected by two opulent citizens of Sparta, to whom they had been betrothed during the life of their father. Plutarch. Cornelius Nepos. Anc. Univer. Hiſt.

LYSANDRIA, Λυσανδρια, in *Antiquity*, a Samian feſtival, celebrated with ſacrifices and games in honour of Lyſander, the Lacedæmonian admiral. It was anciently called *herea*, which name was aboliſhed by a decree of the Samians.

LYSANO, in *Geography*, a town of Pruſſia, in the palatinate of Culm; 15 miles S. of Culm.

LYSE, a town of Norway; 8 miles S.S.W. of Bergen.

LYSEKIL, a ſea-port town of Sweden, in the province of Weſt Gothland; 16 miles W. of Uddevalla.

LYSERUS, Polycarp, in *Biography*, a learned Lutheran divine, was born at Winendeen, in Germany, in 1552. He was educated at the expence of the prince of Wittemburg, and was diſtinguiſhed as well for great induſtry as conſiderable talents. He became diſtinguiſhed as a preacher, and received frequent applications to preach, on particular occaſions, at Vienna, and in other parts of Auſtria. In 1576 he took his degree of doctor of divinity, and in the following year, Auguſtus, elector of Saxony, was induced, by the fame of his pulpit talents, to appoint him a miniſter of the church of Wittemburg. He was ſoon raiſed to the profeſſorſhip of divinity in the univerſity, and attained to other high honours. In the year 1594, he was appointed miniſter of the court of Dreſden, where he ſpent the remainder of his life, occupied not only in literary labours, and in miniſterial duties, but in the education of young princes. He died in 1601, in the forty-ninth year of his age. He was a very voluminous writer, particularly as a commentator on the ſcriptures. He wrote likewiſe ſeveral controverſial treatiſes.

Lyserus, John, a Lutheran divine of the ſame family, diſtinguiſhed for his vaſt zeal as a writer in defence of polygamy. The moſt conſiderable of his publications is entitled "Polygamia Triumphatrix," &c. He ſpent his fortune and his life in endeavours to maintain and propagate his favourite doctrine, and with incredible pains travelled through almoſt every country on the European continent, examining libraries for materials to confirm his ſyſtem. At length, having ſpent all his property, and being reduced to great diſtreſs, he died in the neighbourhood of Paris in 1684. Moreri.

LYSIANTHUS, in *Botany*. (See Lisianthus.) The latter is, no doubt, the original reading in Browne's Jamaica. Lamarck adopts the former, apparently from λυσις, *a diſſolver*, alluding to the deobſtruent or purgative qualities of ſome of the ſpecies deſcribed by Aublet.

LYSIARCHA, an ancient kind of magiſtrate, being the pontiff of Lycia, or ſuperintendant of the ſacred games of that province.

Strabo obſerves, that the lyſiarcha was created in a council conſiſting of the deputies of twenty-three cities; that is, of all the cities in the province; ſome of which cities had three voices, others two, and others but one.

Cardinal Norris ſays, that the lyſiarcha preſided in matters of religion; in effect, the lyſiarcha was nearly the ſame with the *aſiarcha*, and *ſyriarcha*; who, though they were all the heads of the councils, or ſtates of thoſe provinces, yet were they eſtabliſhed principally to take care of the games and feaſts celebrated in honour of the gods, whoſe prieſts they were inaugurated, at the ſame time that they were created *lyſiarcha*, *ſyriarcha*, or *aſiarcha*.

LYSIAS, in *Biography*, an eminent Greek orator, born at Syracuſe about the year 459 B.C. He accompanied his father to Athens while he was very young, and was educated with great care in that city. In proceſs of time he became himſelf a teacher of rhetoric, and compoſed orations for others, but does not appear to have been a pleader. He diſtinguiſhed himſelf by the eloquence and purity of his orations, of which it is ſaid by Plutarch, he wrote no leſs than 425, though the number may with more probability be reduced to 230; and of theſe only 34 remain, which are to be found in the collections of the Greek orators. He died in the 81ſt year of his age, and in the 378th year B.C. Lyſias attained great reputation in his time, which his works afterwards ſupported, and he is mentioned with applauſe by Cicero and Quintilian. Lyſias lived at a ſomewhat earlier period than Iſocrates; and exhibits a model of that manner which the ancients call the "tenuis vel ſubtilis." He has none of the pomp of Iſocrates. He is every where pure and attic in the higheſt degree; ſimple and unaffected; but wants force, and is ſometimes frigid in his compoſitions. In the judicious compariſon which Dionyſius of Halicarnaſſus makes of the merits of Lyſias and Iſocrates, he aſcribes to Lyſias, as the diſtinguiſhing character of his manner, a certain grace or elegance ariſing from ſimplicity: "πεφυκε γαρ ἡ Λυσιου λεξις εχειν το χαριεν· ἡ δ' Ισοκρατους, βουλεται: *i. e.* the ſtyle of Lyſias has gracefulneſs for its nature; that of Iſocrates ſeems to have it." In the art of narration, as diſtinct, probable, and perſuaſive, he holds Lyſias to be ſuperior to all orators; at the ſame time he admits, that his compoſition is more adapted to private litigation than to great ſubjects. He convinces, but he does not elevate nor animate. The magnificence and ſplendour of Iſocrates are more ſuited to great occaſions. He is more agreeable than Lyſias; and in dignity of ſentiment, far excels him. Blair's Lect. vol. ii. The beſt editions of

Lyſias's orations is that by Taylor, London, in 1739, and Cambridge 1740.

Lysia, in *Ancient Geography*, a town of Aſia, in Syria, ſeated on the river Marſyas, W. of the river Orontes, and N.W. of the town of Apamea.—Alſo, a town of Aſia Minor, in Caria, placed by Ptolemy in Phrygia Major.—Alſo, a town of the Peloponneſus, in Arcadia, called alſo *Luſias*.

LYSIMACHIA, in *Botany*, a very ancient generic name, and ſo called, according to Pliny and Ambroſinus, from Lyſimachus, a favourite general of Alexander the Great, who was afterwards king of Thrace. The Engliſh name of this plant, *Looſeſtrife*, is evidently taken from λυσις μαχης, *a diſſolution of ſtrife*, or *a peacemaker*, but how this title could apply to the king on whom it was beſtowed, and who appears to have been of a cruel and ferocious temper, we are at a loſs to imagine, unleſs it were like the ludicrous derivation of *lucus*, a non lucendo. Linn. Gen. 83. Schreb. 109. Willd. Sp. Pl. v. 1. 816. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 227. Ait. Hort. Kew. ed. 2. v. 1. 314. Brown. Prod. Nov. Holl. v. 1. 428. Tournef. t. 59. Juſſ. 95. Lamarck Illuſtr. t. 101. Gærtn. t. 50.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Lyſimachiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, five-cleft, acute, erect, permanent. *Cor.* of one petal, wheel-ſhaped; tube none; limb in five, ovate-oblong, deeply cloven ſegments. *Stam.* Filaments five, awl-ſhaped, oppoſite to the ſegments of the corolla, moſtly united at the baſe; anthers acuminated. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma obtuſe. *Peric.* Capſule globoſe, mucronated, of one cell and ten valves. *Seeds* numerous, angular. *Recept.* globoſe, very large, dotted.

Eſſ. Ch. Corolla wheel-ſhaped. Capſule globoſe, pointed, with ten valves.

Obſ. L. *Linum-ſtellatum* has fruit with only five valves.

Nearly the whole of this genus is pretty well known in our gardens, whilſt ſome of its ſpecies are found to grow ſpontaneouſly in our hedges and fields. It is divided into two ſections, the *firſt* of theſe having many flowers on a ſtalk, the *ſecond* compoſed of ſuch as are ſingle-flowered.—Of the firſt ſection are the following.

L. *vulgaris*. Yellow Looſeſtrife. Linn. Sp. Pl. 209. Engl. Bot. t. 761. Curt. Lond. faſc. 5. t. 19.—Panicled. Cluſters terminal. Leaves ovate-lanceolate, acute.—A native of ſhady, watery places on the banks of rivers, flowering in July.—*Root* perennial, creeping. *Stems* erect, three feet high, leafy, many-flowered. *Leaves* oppoſite, often three or four together, ſpreading, veiny, ſmooth, ſometimes downy. *Cluſters* erect, each partial flower-ſtalk with an awl-ſhaped bractea at its baſe. *Flowers* yellow and handſome.

L. *thyrſiflora*. Tufted Looſeſtrife. Linn. Sp. Pl. 209. Engl. Bot. t. 176.—Flowers in lateral, pedunculated cluſters.—This extremely rare plant, when it does occur, may be found in damp, watery ſituations, in particular parts of Yorkſhire and Scotland. It flowers in July.—*Root* perennial, creeping. *Stems* erect, a foot and half high, perfectly ſimple, round, leafy, ſmooth, now and then woolly. *Leaves* oppoſite, ſeſſile, acute, entire, ſmooth. *Flowers* in axillary, denſe cluſters, ſmall, of a leſs brilliant colour than the laſt. Many parts of the herbage and infloreſcence are prettily ſpotted with red.

Of the remaining ſpecies belonging to this ſection, as they are detailed in Willdenow, none are natives of Britain. They are called L. *decurrens*, *Ephemerum*, *atropurpurea*, *dubia*, and *ſtricta*.

The ſecond ſection compriſes, amongſt others, the following:

L. *nemorum*. Yellow Pimpernel, or Wood Looſeſtrife. Linn. Sp. Pl. 211. Engl. Bot. t. 527. Curt. Lond. faſc. 5. t. 18.—Leaves ovate, acute. Flowers ſolitary. Stem procumbent. Stamens ſmooth.—Found not unfrequently in groves and moiſt ſhady places, flowering from May to September.—*Roots* perennial. *Stems* procumbent, creeping, branched, ſquare, reddiſh, ſhining, leafy. *Leaves* oppoſite, on footſtalks, ovate, entire, ſmooth. *Stalks* axillary, ſolitary, ſingle-flowered, ſlender. *Flowers* delicate, yellow.—This and the following ſpecies may be regarded as two of our moſt ornamental common plants, more eſpecially as their myrtle-like herbage, when intermixed or entangled with ferns or moſs, gives a pleaſing variety to the verdure of rocks, and the banks of rivulets, or ſhady ponds.

L. *Nummularia*. Moneywort, or Herb Twopence. Creeping Looſeſtrife. Linn. Sp. Pl. 211. Engl. Bot. t. 528. Curt. Lond. faſc. 3. t. 14.—Leaves ſomewhat heart-ſhaped. Flowers ſolitary. Stem creeping. Stamens glandular.—A native of the banks of ditches and very moiſt meadows. It flowers copiouſly during the ſummer. *Root* perennial. *Stems* proſtrate, ſquare, compreſſed, generally ſimple. *Leaves* oppoſite, on footſtalks, heart-ſhaped or roundiſh, waved, paliſh green. *Corolla* pale lemon-coloured, and, when magnified, clothed with ſmall glands ſtanding on footſtalks, as are alſo the ſtamens.—The qualities both of this and the preceding are to the beſt of our knowledge perfectly unimportant either for medicinal or agricultural purpoſes.

The remaining ſpecies of *Lyſimachia* are none of them natives. We therefore ſelect two or three of the more intereſting exotic ones.

L. *punctata*. Four-leaved Looſeſtrife. Linn. Sp. Pl. 210. Jacq. Auſtr. t. 366.—Leaves generally four together, almoſt ſeſſile. Stalks verticillate, ſingle-flowered.—Found amongſt reeds in Holland, Auſtria, and other parts of Europe, flowering in July and Auguſt. *Root* perennial, ſomewhat creeping and fibrous. *Stems* two or three feet high, upright, downy, leafy, generally ſimple. *Leaves* ovate-lanceolate, entire, frequently ſpotted with black on the lower ſide. *Flowers* rather ſmall, yellow. The ſegments of the corolla pointed, with tawny dots at their baſe.

L. *quadriflora*. Four-flowered Looſeſtrife. Ait. Hort. Kew. n. 7. Sims in Curt. Mag. t. 660.—Leaves oppoſite, ſeſſile, linear, very long. Stalks four together, terminal, ſingle-flowered.—Sent from North America to Kew garden by Mr. Francis Maſſon in 1798. It flowers like the laſt in July and Auguſt.—*Root* perennial. *Stems* quadrangular, much branched. "*Leaves* oppoſite, linear, quite entire, ſmooth, ſeſſile, longer than the branches. *Branches* axillary to the leaves, ſimilar, terminated with four leaves croſſed, ſerving the office of bracteas; from the axils of each of theſe there riſes a flower-ſtalk, bearing a ſolitary flower, nodding." The ſegments of the corolla are crenate and very ſharply pointed, of a beautiful bright yellow colour; whilſt the whole herbage is of a dark, blackiſh-green. It is a hardy perennial, requiring no particular treatment, even bearing the ſmoke of London without much injury.

L. *ciliata*. Ciliated or Fringed Looſeſtrife. Linn. Sp. Pl. 210. (Lyſimachia canadenſis lutea, folio Jalapæ; Walth. Hort. t. 12.)—Leaf-ſtalks fringed. Flowers drooping.—A native of North America, whence it was introduced by Mr. Philip Miller into this country in 1732. It flowers in July and Auguſt.—*Root* perennial, creeping. *Stems* about two feet high, erect. *Leaves* oblong, ſmooth, acuminate, veined,

veined underneath. *Flowers* axillary, yellow, each on a long, ſlender, naked ſtalk. Linnæus in his *Syſtema Vegetabilium* reckons L. *ciliata* as a variety only of his *quadrifolia*, and in this he is followed by Willdenow, but on the authority of the *Species Plantarum* and *Hortus Kewenſis*, we are inclined to conſider them as diſtinct.

L. *Linum-ſtellatum.* Small Looſeſtrife. Linn. Sp. Pl. 211. (Linum minimum ſtellatum; Magnol. Bot. Monſp. t. 162.) —Calyx longer than the corolla. Stem erect, very much branched.—Not uncommon in France and Italy, where it flowers in the ſpring. *Root* annual, capillary, whitiſh. *Stem* about two or three inches high, very ſlender, much branched. *Leaves* ſeſſile lanceolate, pointed, entire. *Flowers* ſmall, of a pale green colour.

Mr. R. Brown, Prod. Nov. Holl. v. 1. 428, ſuggeſts that this genus ought certainly to be divided. He deſcribes one ſpecies as found near Port Jackſon, L. *maculata*, downy, with ovate leaves, and axillary flowers, whoſe ſtalks are ſhorter than the footſtalks. There is no abſolute certainty of this being diſtinct from L. *japonica* of Thunberg.

LYSIMACHIA, in *Gardening*, comprehends plants of the hardy, herbaceous, biennial, and perennial ſorts, of which the ſpecies moſtly cultivated are, the willow-leaved looſeſtrife (L. ephemerum); the purple flowered looſeſtrife (L. dubia); and the upright looſeſtrife (L. ſtricta.)

Method of Culture.—All theſe plants may be readily increaſed, either by ſowing the ſeeds in the autumnal ſeaſon, as ſoon as they become fully ripe, on a moiſt border which has an eaſtern aſpect; or by parting the roots, and planting them out at the ſame ſeaſon in ſimilar ſituations. The plants ſhould afterwards be kept perfectly clean, and where the firſt mode is uſed, removed into the places where they are to remain during the autumn.

But in the ſecond kind the ſeeds ſhould be ſown upon a hot-bed.

The third ſort is beſt increaſed by planting the bulbs thrown out from the axils of the leaves.

Each of theſe different plants may be employed by way of ornament and variety in the clumps, borders, and other parts of gardens and pleaſure grounds.

LYSIMACHIA, in *Ancient Geography*, a town of Thrace, called in the time of Ptolemy *Xamilium*.

LYSIMACHIA *Worm*, in *Natural Hiſtory*, a name given to an inſect found very frequently feeding on the leaves of the *lyſimachia*, or willow-herb. It has uſually been eſteemed a caterpillar, but is properly one of the fauſſe chenilles, having a rounded head, and twenty-two legs; this creature changes its ſkin ſeveral times, and finally changes its colour with it; it is at firſt of a blueiſh-grey, but on its laſt change in the worm-ſtate it becomes of a yellowiſh-green; when it has lived a week, or thereabout, after this laſt change, it becomes a chryſalis, from which there afterwards comes out a four-winged fly.

LYSIMACHIÆ, in *Botany*, an elegant Natural Order of plants, named from the *Lyſimachia*, which is one of them; ſee that article. This order is the firſt in Juſſieu's eighth claſs. See LABIATÆ and GENTIANÆ.

The *Lyſimachiæ* are thus defined.

Calyx divided. *Corolla* generally regular, its limb divided, moſtly into five lobes. *Stamens* define, moſtly five, rarely either more or fewer, being equal in number to, and placed againſt, the ſegments of the corolla. *Style* ſolitary; ſtyle ſimple, or rarely cloven. *Fruit* of one cell with many ſeeds, often capſular, the receptacle of the ſeeds central, unconnected with the valves. *Stem* herbaceous. *Leaves* either oppoſite or alternate.

Section 1, conſiſting of plants whoſe flowers are borne on a leafy ſtem, contains *Centunculus*, *Anagallis*, *Lyſimachia*, *Hottonia*, *Coris*, *Sheffieldia*, *Limoſella*, *Trientalis*, and *Aretia*.

Section 2, comprehends plants whoſe flower-ſtalks ſpring directly from the root, as well as the leaves, and are generally umbellate, with a many-leaved involucrum; ſometimes however they are ſimple and ſingle-flowered. The genera are *Androſace*, *Primula*, *Cortuſa*, *Soldanella*, *Dodecatheon*, and *Cyclamen*.

Juſſieu ſubjoins a 3d Section, of plants akin to the *Lyſimachiæ*. Theſe are *Globularia*, ſurely miſplaced here; *Conobea* of Aublet; *Tozzia*, which two laſt we ſhould rather have referred to the order of *Pediculares*; *Samolus*, *Utricularia*, *Pinguicula*, and *Menyanthes*.

M. Ventenat has choſen to call this order *Primulaceæ*, and he is followed by Mr. Brown. The latter name is perhaps preferable, and there ſeems to be nothing fixed as yet amongſt the ſtudents of natural orders, as to names or their terminations. The ſcience is new and experimental at preſent, and rigid laws ſhould not prevent improvements. It is far otherwiſe with names of genera and ſpecies, which are the current coin, not the paper currency, of the botanical realm.

LYSIMACHUS, in *Biography*, king of Thrace, one of the captains of Alexander the Great, roſe from a very mean condition to the favour of that prince. At the partition of the empire of Alexander, in the year 323 B.C., Thrace, the Cherſoneſe, and the countries adjacent to the Euxine, were allotted to Lyſimachus. When Antigonus had rendered himſelf formidable to all the other ſharers, Lyſimachus joined in the league againſt him, with Seleucus, Ptolemy, and Caſſander. By a ſubſequent treaty, Thrace was confirmed to him; and in imitation of other captains, he took the title of king. He founded the city of Lyſimachia in 309 B.C., and made it his capital. In conjunction with Seleucus, he gained the great battle of Ipſus. He afterwards ſeized upon Macedonia, having firſt expelled Pyrrhus from the throne; but his cruelty rendered him truly odious, and the murder of his ſon Agathocles ſo offended his ſubjects, that the moſt opulent and powerful revolted from him, and abandoned the kingdom. He purſued them into Aſia, and declared war againſt Seleucus, who had given them a kind reception. He was killed in a bloody battle, in the 281ſt year B.C., and in the 80th of his age. His body was found in the heaps of ſlain by the fidelity of his dog, which had carefully watched near it. With great courage and abilities, he was characterized by a cruel and ferocious diſpoſition, which rendered him unworthy of his high fortune. Juſtin mentions a curious fact concerning him, *viz*, that having offended Alexander, he was, as a puniſhment, thrown into the den of a furious lion; and when the ravenous animal darted upon him, he wrapped his hand in his mantle, and boldly thruſt it into the lion's mouth, and by twiſting his tongue, killed an adverſary ready to devour him. This act of courage in ſelf-defence recommended him to the monarch, who pardoned and took him into his favour. Univer. Hiſt.

LYSINE, in *Ancient Geography*, a town of Aſia, in Pamphylia, between Comana and Cormaſa, according to Ptolemy.

LYSINEMA, in *Botany*, from λυσις, *a ſeparation*, and νημα, *a thread* or *ſtamen*, becauſe the ſtamens are unconnected with the corolla, proceeding from the receptacle, below the germen, by which character alone the genus is diſtinguiſhed from *Epacris*, their habit being exactly the ſame. The tube of the corolla however is generally divided, more or leſs deeply, into five parts in *Lyſinema*. Brown Prodr.

Nov. Holl. v. 1. 552.—Claſs and order, *Pentandria Monogynia.* Nat. Ord. *Epacrideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of many erect, imbricated, coloured, permanent leaves; the inner ones gradually largeſt. *Cor.* of one petal, ſalver-ſhaped; its tube generally ſplitting into five parts; limb in five ſmooth beardleſs ſegments, obliquely twiſted to the right. Nectary of five glands, ſurrounding the baſe of the germen. *Stam.* Filaments five, thread-ſhaped, equal, inſerted into the receptacle; anthers incumbent, oblong, burſting lengthwiſe, riſing juſt above the tube. *Piſt.* Germen ſuperior, roundiſh, with five furrows; ſtyle thread-ſhaped; ſtigma obtuſe. *Peric.* Capſule of five cells and five valves. *Seeds* numerous, minute. *Receptacles* five, attached to the central column.

Eſſ. Ch. Calyx of many imbricated coloured leaves. Corolla ſalver-ſhaped; its limb five-cleft, beardleſs. Stamens inſerted into the receptacle, the length of the tube. Capſule of five cells, with many ſeeds.

1. L. *pentapetalum.* Corolla divided to the bottom; its claws unconnected, longer than the calyx, externally ſmooth.—Found by Mr. Brown in the ſouthern part of New Holland.

2. L. *ciliatum.* Corolla divided to the bottom; its claws cohering at the top, externally ſmooth, the length of the calyx.—Native of the ſame country. We have ſeen neither of theſe.

3. L. *laſianthum.* Corolla divided to the bottom; its claws externally woolly, rather longer than the calyx.—Gathered by Mr. Menzies at King George's Sound, on the ſouth-weſt coaſt of New Holland. The *ſtem* is ſhrubby, as in all the reſt, its branches very ſlender, ſmooth, round, leafy. *Leaves* ſcattered, about a quarter of an inch long, elliptic-oblong, narrow, obtuſe, entire, ſmooth; flat above; convex beneath. *Footſtalks* ſhort, ſmooth. *Flowers* few, in a terminal ſimple ſpike, leaning one way, apparently tawny or bluſh-coloured, each near half an inch long. *Calyx-leaves* blunt, with a membranous edge; the inner ones fringed. *Petals* obtuſe.

4. L. *conſpicuum.* Tube of the corolla five-cleft above, longer than the calyx. Leaves lanceolate-awl-ſhaped, cloſe-preſſed.—Found by Mr. Brown in the ſouth of New Holland.

5. L. *pungens.* (Epacris pungens; Cavan. Ic. v. 4. 26. t. 346.)—Tube of the corolla undivided, the length of the calyx. Leaves ſpreading, ovate, ſharp-pointed.—Native of the country about Port Jackſon, New South Wales, from whence ſpecimens were ſent in 1791 by Dr. White. The *ſtem* is woody, with many ſtraight rigid branches, thickly beſet with ſeſſile, rigid, ſmooth, entire, ribbed, ſpinous, and taper-pointed *leaves;* their baſe ovate or heart-ſhaped, cloſe-preſſed, and partly claſping the ſtem; the reſt ſpreading nearly horizontally, very pungent. *Flowers* white and fragrant, very elegant, in denſe, leafy, terminal ſpikes. Segments of the *corolla* pointed, ſomewhat plaited when dry. *Style* prominent, hairy. We have already ſpoken of this ſhrub as *Epacris pungens.* (See Epacris.) Mr. Brown ſubjoins Dr. Sims's red-flowered plant, Curt. Mag. t. 1199, as a variety, and he adds that this *L. pungens* is an intermediate ſpecies, as it were, between *Lyſinema* and *Epacris.* It agrees with the latter in its corolla, but has the inſertion of the ſtamens proper to the former.

LYSIPPUS, in *Biography*, a celebrated ſculptor and ſtatuary, was born at Sicyon, and flouriſhed in the time of Alexander the Great. He was originally a worker in braſs, and then applied himſelf to painting, till his talents and inclination led him to fix on the profeſſion of a ſculptor. He worked with ſuch extraordinary diligence and facility, that he is ſaid to have left 1500 performances, all of ſuch excellence, that any one of them ſingly might have conferred celebrity on him as an artiſt. He attained to ſo high a reputation, that Alexander forbad any ſculptor but Lyſippus to make his ſtatues. Lyſippus improved the art of ſtatuary by a better imitation of the hair, and by an attentive ſtudy of ſymmetry, in which he conſidered how the human figure appeared to the eye, not what were its exact proportions. The moſt admirable of his works were the ſtatues of Alexander, of which he executed a ſeries, beginning from his childhood: one of a man coming out of a bath, placed by Marcus Agrippa before his public baths; and being removed by Tiberius into his own chamber, the Roman people were ſo clamorous for its reſtitution, that the emperor thought it prudent to comply with their wiſhes. A chariot of the ſun at Rhodes was one of his great works, which was, however, ſurpaſſed by a coloſſus at Tarentum 40 cubits high. His ſtatue of Socrates, and thoſe of the twenty-five horſemen who were drowned in the Granicus, were ſo highly valued, that, in the age of Auguſtus, they were ſold for their weight in gold.

LYSIS, a Pythagorean philoſopher, who flouriſhed in the fifth century before Chriſt, was a native of Tarentum, who, according to Jamblichus, was inſtructed in his philoſophy by Pythagoras himſelf. Being well initiated and excelling in the doctrines of his maſter, he opened a ſchool for the purpoſe of inſtructing others, but would never admit perſons of bad character among his auditors. He even refuſed, on that account, entrance to Cylon, one of the wealthieſt people of the city. Cylon was exaſperated at the neglect, as he thought it, and reſolved on revenge. He cauſed the houſe of Milo, in which Lyſis and forty other Pythagoreans were aſſembled, to be ſet on fire; meaning by the violence of a hired mob to aſſaſſinate thoſe, by bludgeons or miſſile weapons, who ſhould eſcape burning. Excepting Lyſis and Archippus, they were every one burnt or ſtoned to death. The philoſopher now retired, firſt into Achaia, and afterwards to Thebes, where he opened a ſchool, and remained an uſeful inſtructor to the Grecian youth till he died. Among other famous diſciples he could, it has been ſaid, mention Epaminondas; though others ſeem to doubt the fact, and to be deſirous of referring that honour to another perſon of the ſame name. Lyſis is celebrated for having been a moſt exact and punctual performer of his promiſes, even on the moſt trivial occaſions. He compoſed Commentaries on the philoſophy of Pythagoras, which have not come down to our times. Some writers have attributed to him the "Golden Verſes;" while others have given them to Philolaus, or Empedocles. There is ſtill extant, under the name of Lyſis, a letter addreſſed to Hipparchus, in which the latter is reproached for having divulged the ſecrets of the Pythagorean philoſophy. It may be found in the "Opuſcula Mythologica et Philoſophica" of Dr. Thomas Gale.

LYSKO, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 52 miles S.W. of Novogrodek.

LYSOBYKI, a town of Poland, in the palatinate of Lublin; 20 miles N.N.W. of Lublin.

LYSSA, Λυσσα, a word uſed by medical authors to expreſs that ſpecies of madneſs which is peculiar to dogs and wolves, but is communicated by their bite to man and other animals. Hence perſons labouring under the diſmal effects of ſuch a bite, are called alſo *lyſſodecti.*

LYSSENDORF, in *Geography*, a town of France, in the department of the Sarre, and chief place of a canton, in the diſtrict of Prum. The place contains 117, and the canton 1962 inhabitants, in 25 communes.

LYSTRA, a ſmall town of America, in Nelſon county, Kentucky, ſituated on a weſt water of Rolling Fork, a ſouth branch of Salt river. N. lat. 37° 25′.

LYSWIK, a town of Sweden, in the province of Warmeland; 34 miles N. of Carlſtadt.

LYTHRUM, in *Botany*, the λυθρον of Dioſcorides, moſt probably received its name from the purple tinge of its flowers: λυθρον ſignifying *clotted*, or *gore blood*, to which ſubſtance this plant is ſimilar in colour. Linn. Gen. 240. Schreb. 323. Willd. Sp. Pl. v. 2. 865. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 509. Ait. Hort. Kew. ed. 2. v. 3. 149. Juſſ. 332. Lamarck Illuſtr. t. 408. Gærtn. t. 62. (Salicaria; Tournef. t. 129.)—The *Cuphea* of Brown, in his hiſtory of Jamaica, united to *Lythrum* by Linnæus, is now by general conſent ſeparated, on account of its irregular flower, and capſule with a ſingle cell.—Claſs and order, *Dodecandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Salicariæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cylindrical, ſtriated, with twelve teeth, the alternate ones leſs. *Cor.* Petals ſix, oblong, rather obtuſe, ſpreading, inſerted into the baſe of the ſegments of the calyx. *Stam.* Filaments twelve, thread-ſhaped, the length of the calyx; the upper ones ſhorter than the lower; anthers ſimple, ſomewhat aſcending. *Piſt.* Germen ſuperior, oblong; ſtyle awl-ſhaped, the length of the ſtamens, declining; ſtigma orbicular, aſcending. *Peric.* Capſule oblong, pointed, covered by the calyx, of two cells. *Seeds* numerous, ſmall.

Eſſ. Ch. Calyx inferior, with twelve teeth. Petals ſix, inſerted into the calyx. Capſule with two cells and many ſeeds.

Obſ. In ſome ſpecies of *Lythrum*, one-ſixth of the parts of fructification is found to be deficient; in others only ſix ſtamens are to be ſeen.—We deſcribe the following principal ſpecies as a ſufficient illuſtration of the genus.

L. *Salicaria*. Purple Lythrum. Linn. Sp. Pl. 640. Engl. Bot. t. 1061. Curt. Lond. faſc. 3. t. 28.—Leaves oppoſite, lanceolate, heart-ſhaped at the baſe. Flowers ſpiked. Stamens twelve. A native of marſhes and the banks of rivers, flowering in July and Auguſt.—*Root* perennial, woody, throwing up many ſtems. *Stems* three feet high, erect, wand-like, quadrangular (occaſionally hexangular) leafy. *Leaves* oppoſite, ſometimes, though rarely, three or four together, ſtill more rarely alternate, ſeſſile, ſmooth above, downy at the margin and underneath. *Flowers* in a whorled ſpike, purple.—One of our moſt ſhowy wild plants, and extremely ornamental to the banks of ditches, ponds, and rivers, though occaſionally to be met with in drier ſituations.

L. *virgatum*. Fine-branched Lythrum. Linn. Sp. Pl. 642. Jacq. Auſtr. t. 7. Curt. Mag. t. 1003.—Leaves oppoſite, lanceolate. Panicle ſtraight. Flowers three together.—Originally found by Cluſius in Auſtria, and in the iſles of the Danube. It was introduced by Jacquin into the gardens at Kew in 1776, where it flowers from June to September.—*Root* perennial, thick. *Stems* upright; at the bottom, round, pale-brown mixed with green, generally leafleſs; towards the top ſquare, leafy and branched. *Leaves* oppoſite, thickiſh, nearly ſeſſile. *Flowers* ſix in a whorl, the lower ones more remote, all axillary, of a deep purple colour.—Linnæus notices a variety of *L. virgatum* which has fewer flowers in the whorl, and whoſe leaves are alternate.

L. *hyſſopifolium*. Hyſſop-leaved Lythrum, or Graſs-poly. Sm. Fl. Brit. 510. Engl. Bot. t. 292. (L. Hyſſopifolia; Linn. Sp. Pl. 642. Jacq. Auſtr. t. 133.)—Leaves alternate, linear-lanceolate. Stamens ſix.—A rare Engliſh plant, to be met with occaſionally in moiſt places where water has ſtagnated through the winter. Common in many other parts of Europe, flowering in Auguſt.—*Root* annual, ſimple, attenuated. *Stem* a ſpan high, branched at the baſe, erect. *Leaves* ſmooth, varying in breadth; the lower ones only, oppoſite. *Flowers* axillary, almoſt ſeſſile, ſolitary, ſmall, purple, hexandrous, though occaſionally five-cleft and pentandrous.

LYTHRUM, in *Gardening*, contains a plant of the hardy, herbaceous, perennial kind, of which the ſpecies cultivated is the common or purple willow-herb (L. Salicaria.)

Method of Culture.—This ſort and varieties may be readily increaſed by parting the roots in autumn, and planting them out in the ſituations where they are to remain. They may likewiſe be raiſed from ſeed ſown at the ſame time, but the firſt is the readieſt method. They delight in rather moiſt ſoil.

All of them are highly ornamental in the larger borders, clumps, and other parts of pleaſure-grounds, being placed towards the back parts, from their full growth.

LYTTA, or LYTTA *Veſicatoria*, in the *Materia Medica*, the name given to the Bliſtering Fly.

The *Ceratum Lyttæ*, or *Ceratum Cantharidis* of P. L. 1787, is compoſed of ſpermaceti cerate, and bliſtering flies, in a very fine powder, in the proportion of ſix drachms of the former to a drachm of the latter, and is prepared by ſoftening the cerate by heat, adding the flies, and mixing them together.

LYTTÆ, *Emplaſtrum*. See EMPLASTRUM.

LYTTÆ, *Tinctura*, *Tinctura Cantharidis*, P. L. 1787, tincture of bliſtering fly, is prepared by macerating for 14 days three drachms of bliſtering flies bruiſed, in two pints of proof ſpirit. In order that this preparation may be certain in its effects, it is neceſſary that the inſects ſhould be freſh and perfect: for want of attention to this circumſtance, large doſes have been given without any ſenſible effect. See BLISTER and CANTHARIDES.

LYTTA, in *Natural Hiſtory*, a genus of inſects, of which there are thirty-two ſpecies enumerated in Gmelin's edition of the Syſt. Nat. The generic character is antennæ filiform; four unequal feelers, the hind ones clavate; thorax roundiſh; head inflected gibbous; ſhells ſoft, flexile, as long as the abdomen. All the ſpecies of this genus are exotics, and ſcattered through the globe, as will be ſeen in the following enumeration: many of them reduced to powder are capable of veſiccating the ſkin on application to the ſurface of the body.

Species.

VESICATORIA; Bliſter-fly. Green; antennæ black. This is the common Cantharis veſicatoria, or Spaniſh-fly of the ſhops: though the inſect has been uſually ranked under the genus Meloe, and has, indeed, been ſo referred to from the article BLISTER in our own work: it is found to have no claim as belonging to that genus, and we have accordingly reſtored it to its proper place. It inhabits many parts of Europe, on aſh and elder trees. It is uſed for various purpoſes in pharmacy, but chiefly for raiſing bliſters; it multiplies greatly, and has a nauſeous ſmell. The odorous particles are extremely corroſive. The female inſect, after impregnation, depoſits her eggs in the ground, where they remain till they have undergone the various changes that are to bring forth the winged inſects.

SEGETUM. Golden; ſhells green. This is a leſs ſpecies than the Veſicatoria; is found in Barbary among corn. The antennæ are black; head and thorax ſometimes golden, ſometimes green with a gloſs of gold ; body golden ; legs duſky.

Nitidula. Green bronzed ; ſhells teſtaceous ; antennæ black. This ſpecies has been ſometimes deſcribed as belonging to the Engliſh inſects ; but Gmelin deſcribes it as inhabiting the Cape only.

Collaris. Black ; crown, thorax, and legs ferruginous ; the ſhells are of an azure colour. This is a large inſect, and is found in the ſouthern parts of Ruſſia. The antennæ are ferruginous ; edge of the thorax a little black. The male is as ſmall again as the female.

Gigas. Azure ; breaſt ferruginous ; it inhabits Guinea. The ſize of this inſect is about the ſame as that of the L. veſicatoria ; one ſex has the ſhells ſtriate, but in the other they are ſmooth.

Syriaca. Villous, green-blue ; thorax rounded and ferruginous. It inhabits the ſouthern parts of Europe.

Ruficollis. An inhabitant of the Eaſt Indies. Glabrous, green-gold ; thorax rufous, tapering before.

Testacea. Above teſtaceous ; ſhells with a large oblong black ſpot near the tip. It inhabits Tranquebar. The head is teſtaceous ; mouth and antennæ black ; thorax punctured and teſtaceous ; ſhells ſmooth ; body black.

Festiva. Shining braſſy-green ; ſhells teſtaceous with ſpots of braſſy-green. The body is entirely green bronze ; ſpot on the ſhells varying. Inhabits Siberia.

Marginata. Black ; margins of the ſhells pale cinereous ; inhabits the Cape of Good Hope ; above opaque, beneath cinereous.

Vittata. Shells black, with a yellow margin ; an inhabitant of America. By ſome entymologiſts this is deſcribed as the Cantharis vittata. Head yellowiſh ; crown with two black ſpots ; thorax black, with three yellow lines ; abdomen and legs black.

Atrata. Body black, immaculate ; inhabits Barbary, and is the Meloe pennſylvanica of ſome writers. About half the ſize of the Vittata, and entirely of a deep black.

Erythrocephala. Black ; head teſtaceous ; thorax and ſhells with cinereous lines. This ſpecies is found in ſeveral parts of Auſtria ; the head is teſtaceous, with a black line down the middle ; mouth black ; thorax channelled.

Oculata. Black, with a yellow callous dot behind the eyes ; inhabits Guinea. Body entirely black immaculate ; behind the eyes on each ſide is a large raiſed yellow dot. Female apterous, ſhells abbreviated.

Dubia. Black ; crown fulvous ; thorax and ſhells immaculate. Inhabits Siberia ; and is the Meloe algiricus of ſome entomologiſts.

Afra. Black ; thorax rufous ; this ſpecies is found in Africa ; and is the Cantharis afra of Olivier.

Hæmorrhoidalis. Blackiſh blue ; end of the abdomen rufous ; the antennæ are black ; head and thorax villous ; body blueiſh.

Quadrimaculata. Black, glabrous ; breaſt downy ; ſhells yellowiſh-grey, with two black and almoſt ſquare ſpots. A native of the northern parts of Aſia ; is found among flowers ; and it exudes a very pleaſant ſmelling oil from its legs. This is a circumſtance attaching likewiſe to the

Fenestrata, which is glabrous, pale teſtaceous ; thorax depreſſed ; ſhells grey tipt with black, have two ſquariſh hyaline ſpots ; found alſo in the Aſiatic parts of Siberia, chiefly among flowers.

Clematidis. Black, with a ſteel-blue gloſs ; ſhell pale teſtaceous immaculate ; found on the clematis in Siberia.

Uralensis. Black, opaque, glabrous ; this is often confounded with the Atrata above deſcribed, and is not ſufficiently diſtinct from it. An inhabitant of Siberia.

Sibirica. Black, opaque, glabrous ; ſhells edged with white ; head red ; eyes, mouth, and antennæ black. Is found on the lotus in divers parts of Siberia. Middle joints of the antennæ, in the male, compreſſed and armed with a tooth.

Lutea. Black, woolly ; ſhells ventricoſe, ſubcompreſſed, pale yellow with ſix black dots. Inhabits Siberia.

Ocellata. Black, woolly ; legs teſtaceous ; head, thorax, and ſhells yellowiſh, the latter with ſix ocellate black ſpots in the middle. Inhabits the Caſpian ſea, and has been deſcribed particularly by Pallas. Like the "Four-ſpotted" and "Feneſtrata", it exudes an agreeable oil from its legs.

Pectinata. Antennæ pectinate ; body black ; front red. It inhabits Siberia.

Cinnabarina. Black ; thorax above, ſhells, and head on each ſide red. Inhabits Carniola.

Rufa. Black ; head rufous. Inhabits Carniola.

Subvillosa. Yellowiſh ſubvillous ; antennæ tapering. Is found in many parts of France.

Bicolor. Teſtaceous ; ſhells tipt with black. Inhabits France.

Formicaria. Brown ; the fore-part of the elytra, and the thorax, which is elongated, are red. This is found in France and other parts of Europe.

Pubescens. Black ; head and thorax pubeſcent ; ſhells yellow, with a ferruginous ſpot on each ſide behind ; this inſect has been found only in muſeums by modern naturaliſts.

Ferruginea. Ferruginous ; head and thorax rufous ; ſhells brown teſtaceous at the baſe. Inhabits various parts of Europe.

LYTTELTON, George, *Lord*, in *Biography*, was the eldeſt ſon of ſir Thomas Lyttelton, bart. of Hagley, in Worceſterſhire, where he was born in January 1708-9. He was educated at Eton, from which place he was removed to Chriſt-church college, Oxford. He was from an early age diſtinguiſhed for his proficiency in claſſical learning, and ſome of his poems were the fruit of his youthful ſtudies. When he had completed his courſe at Oxford, he ſat out upon a tour to the continent, and his letters to his father during his abſence are replete with remarks diſplaying ſolid judgment and ſound principles, while, at the ſame time, they afford a moſt pleaſing example of filial affection and duty, joined with the unreſerved confidence of intimate friendſhip. During his reſidence abroad, he wrote a poetical epiſtle to Dr. Ayſcough, which is thought to be one of the beſt of his works, and another to Pope, elegantly complimentary of that great poet. Upon his return from the continent, he was choſen repreſentative, in parliament, for the borough of Oakhampton. At this time his father was a ſupporter of the exiſting miniſtry under Walpole. The ſon, animated with that patriotic ardour, which ſcarcely ever fails to inſpire the boſom of virtuous and liberal youth, and which it is almoſt diſcreditable for a young man not to feel, took a contrary part, and diſtinguiſhed himſelf among the oppoſers of adminiſtration. His name is to be found among thoſe of the minority in almoſt every important debate, and he zealouſly concurred in every meaſure adopted by Pulteney, Pitt, and other leaders of that party. In 1735 he publiſhed his "Perſian Letters," of which it appears, by the teſtimony of Dr. Warton, he was rather aſhamed at the cloſe of life. Mr. Lyttelton obtained the notice and friendſhip of Frederic prince of Wales, and was appointed ſecretary to his royal highneſs ; by his inſtigation it is imagined the prince aſſumed the patronage of letters, the beneficial effect of which Mallet, Thomſon, and others experienced. It was probably on this account that Pope gave him the praiſe of pure patriotiſm, rather than from any regard to his political principles:

> "Free as young Lyttelton her cauſe purſue;
> Still true to virtue, and as warm as true."

On the death of Thomſon, who left his affairs in a very embarraſſed condition, Mr. Lyttelton took that poet's ſiſter under his protection. He reviſed the tragedy of Coriolanus, and brought it out at the theatre-royal Covent-garden, with a prologue of his own writing, in which he ſo affectingly lamented the loſs of that bard, that not only Quin, who ſpoke the lines, but the whole audience, ſpontaneouſly burſt into tears. He had married, in 1742, Lucy, daughter of Hugh Forteſcue, eſq. and enjoyed in her ſociety the moſt unalloyed happineſs, which was miſerably interrupted by her death in 1746, leaving him one ſon, Thomas, the late lord, and a daughter, Lucy, who married lord Valentia. On the monument of his beloved lady, he inſcribed the following lines.

> "Made to engage all hearts, and charm all eyes:
> Tho' meek, magnanimous; tho' witty, wiſe;
> Polite, as all her life in courts had been;
> Yet good, as ſhe the world had never ſeen:
> The noble fire of an exalted mind,
> With gentleſt female tenderneſs combin'd.
> Her ſpeech was the melodious voice of love
> Her ſong the warbling of the vernal grove.
> Her eloquence was ſweeter than her ſong,
> Soft as her heart, and as her reaſon ſtrong.
> Her form each beauty of her mind expreſſ'd
> Her mind was virtue by the Graces dreſſ'd."

Beſides theſe lines, her affectionate huſband wrote a monody on her death, which diſplays much natural feeling amidſt the more elaborate ſtrains of a poet's imagination.

On the expulſion of Walpole from the miniſtry, Lyttelton, in 1744, was appointed one of the lords of the treaſury. He was always aſſiduous in his parliamentary attendance, and a vigorous ſupporter of the meaſures in which he partook, but never attained the ſtation of leader. He ſpoke with eaſe and fluency, but was not eloquent in the uſual ſenſe of the word. In early life, he ſeems to have entertained ſtrong doubts of the truth of revelation, probably from the corruptions of it, which he had witneſſed on the continent, but upon ſerious and impartial inquiry he became a firm believer in Chriſtianity, and wrote in its defence, "A Diſſertation on the Converſion of St. Paul," which has ever been regarded as a maſterly performance. This piece was written at the deſire of Gilbert Weſt, eſq. in conſequence of Mr. Lyttelton's aſſerting, that, beſides all proofs of the Chriſtian religion, which might be drawn from the prophecies of the Old Teſtament, from the neceſſary connection it has with the whole ſyſtem of the Jewiſh religion, from the miracles of Chriſt, and from the evidence of his reſurrection by all the other apoſtles, he thought the converſion of St. Paul alone, was of itſelf a demonſtration ſufficient to prove Chriſtianity to be a divine revelation.

In 1749 he married again, but the conduct of his ſecond wife proved ſo little to his ſatisfaction, that a ſeparation by mutual conſent enſued in a very ſhort time. By the death of his father in 1751, he ſucceeded to the title and eſtate. His taſte for rural ornament he diſplayed at Hagley, which he rendered one of the moſt delightful places in the kingdom. He occupied ſeveral poſts under government, but at the diſſolution of the miniſtry in 1759 he went out of office, and was, as a reward for his ſervices, raiſed to the honour of a peerage, under the ſtyle and title of baron Lyttelton, of Frankley, in the county of Worceſter.

From this period he chiefly devoted himſelf to the purſuits of literature, and to an extenſive correſpondence with the pious and learned. In 1760 he publiſhed "Dialogues of the Dead," a work abounding in good ſenſe and ſound morality, and which was well received by the public. In 1767 and 1771 he gave the world his "Hiſtory of Henry II., in three vols. 4to." a valuable work, which had occupied a great portion of the latter part of his life, and on which he probably placed his chief expectations for future fame. He has given an accurate and comprehenſive view of the Engliſh conſtitution, as it exiſted at the early period of our hiſtory with which his book is concerned, and of the changes ſubſequent to the Norman conqueſt. The ſtyle of the hiſtory is good; its ſentiments are judicious and liberal, favourable to the beſt intereſts of mankind. The poems of this nobleman preſerve a place among the ſelect productions of the Britiſh muſe, rather on account of the correctneſs of their verſification, the elegance of their diction, and the delicacy of their ſentiments, than as exhibiting any uncommon poetical powers. As a politician, his ſpeeches on the Scotch and mutiny bills, in 1747; on the naturalization of the Jews in 1753; and on the privilege of parliament in 1763, hold him out to public eſtimation. He died in Auguſt 1773, in the 64th year of his age. His miſcellaneous works were publiſhed after his death in one volume 4to. His lordſhip, among other qualities, had a remarkable facility of ſtriking out an extemporary compliment, which obtained for him a conſiderable ſhare of reputation; an inſtance is recorded, when lord Cobham, in a large company, mentioned his deſign of putting up a buſt of lady Suffolk in his beautiful gardens at Stowe, he turned to his friend Lyttelton and ſaid "George, you muſt furniſh me with a motto for it." I will, ſaid he, and inſtantly produced the couplet;

> "Her wit and beauty for a court were made,
> But truth and goodneſs fit her for a ſhade."

Johnſon's Lives of the Poets.

Lyttelton, Charles, an Engliſh prelate, brother of the above, was educated at Eton in grammar learning, from whence he entered himſelf at Univerſity college, Oxford, and afterwards ſtudied the law in the Temple and was called to the bar. He, however, ſoon quitted the profeſſion, entered into holy orders, and in 1747 was appointed chaplain to the king. The year following he was made dean of Exeter, and in 1762 promoted to the biſhopric of Carliſle. He was ſeveral years preſident of the Society of Antiquaries, and contributed ſeveral articles to their Tranſactions. He died in 1768.

M.

M, A liquid conſonant, and the twelfth letter in the alphabet.

It has one unvaried ſound, and is pronounced by ſtriking the upper lip againſt the lower; in which the pronunciation of this letter agrees with that of *b*; the only difference between the two conſiſting in a little motion made in the noſe in pronouncing M, and not in *b*: whence it happens, that thoſe who have taken cold, for M ordinarily pronounce *b*; the noſe, in that caſe, being diſabled from making the neceſſary motion.

All conſonants are formed with the aid of vowels; in *em* the vowel precedes, in *be* it follows: and M is never mute.

Quintilian obſerves, that the M ſometimes ends Latin words, but never Greek ones; the Greeks always changing it in that caſe into *n*, for the ſake of the better ſound.

M is alſo a numeral letter, and among the ancients was uſed for a thouſand; according to the verſe,

> “ M caput eſt numeri, quem ſcimus mille teneri.”

When a daſh is added at the top of it, as $\overline{\text{M}}$; it ſignifies a thouſand times a thouſand.

M, as an abbreviature, ſtands for Manlius, Marcus, Martius, and Mucius: M.A. ſignifies *magiſter artium*, or maſter of arts; MS. manuſcript, and MSS. manuſcripts.

M, in *Aſtronomical Tables*, and other things of that kind, is uſed for *Meridional*, or ſouthern; and ſometimes for *Meridian*, or mid-day.

M, in *Medicinal Preſcription*, is frequently uſed to ſignify a maniple, or handful: and it is ſometimes alſo put at the end of a recipe, for *miſce*, *mingle*; or for *mixtura*, *a mixture*. Thus, *m. f. julapium*, ſignifies *mix*, and *make a julep*.

M, in *Law*, the brand or ſtigma of a perſon convicted of man-ſlaughter, and admitted to the benefit of his clergy.

It is to be burnt on the brawn of his left thumb.

M, in *Muſic*. This letter in old pſalm-tunes, harmonized, ſtands for *mean*, or middle part, the ſecond treble, and ſometimes the counter-tenor. In Scarlatti's leſſons compoſed in Spain, it implies *mano manca*, or left hand.

MA, in *Hindoo Mythology*, is a name of Parvati, the conſort of Siva, as noticed under thoſe articles.

MAA, in *Geography*, a town of Hindooſtan, in Dowlatabad; five miles N.E. of Beder.

MAAB, a ſettlement of Weſt Greenland. N. lat. 62° 6′. W. long. 48° 30′.

MAACAH, Macaati, or *Beth-Maacha*, in *Ancient Geography*, a little province of Syria, E. and N. of the ſources of Jordan, toward Damaſcus. We learn from Joſhua (xiii. 13.) that the Iſraelites would not deſtroy the Maachathites, but permitted them to dwell in the land; and from Deut. iii. 14. and Joſh. xii. 5, that the lot of the half tribe of Manaſſeh beyond Jordan extended to the country. Hence the ſmall canton, near the head of Jordan, on the E. ſide of it, in the way to Damáſcus, was called Maachonitis, or Machonitis.

MAADEN al Nocra, in *Geography*, a town of Arabia Felix, in the province of Hedjas; 140 miles E. of Hagiaz.

Maaden *Uzzumurud*, the *Mine of Emeralds*, a mountain of Egypt, on the coaſt of the Red ſea; 90 miles S. of Coſſeir.

MAADIE′, denoting *Paſſage*, is the name of a village conſiſting of two or three houſes, upon the E. bank of the Nile, ſo called becauſe they ſtand at the place facing the uſual *paſſage* to the Delta. Dr. Shaw conceived this to be the ſcite of the ancient Heraclea, but Sonnini made diligent examination on this ſpot, and could perceive no veſtiges of buildings of a remote time, but half a league further, he remarked upon the coaſt old walls and ruins, which may be traced a long way into the ſea, and which are probably the remains of Heraclea or Heracleum. Maadié is diſtant about ſix leagues from Alexandria, on a lake of the ſame name, which is the extremity of the Canopic branch of the Nile. The lake communicates with the Mediterranean by a narrow opening, at which the French raiſed a block-houſe, from which they were driven by the Britiſh, under lieut. Brown. Maadié is five miles E. of Aboukir.

MAAGRUNNI, two iſlands on the E. ſide of the gulf of Bothnia. N. lat. 65° 25′. E. long. 24° 56′.

MAALMORIE, a cape of Scotland, on the S.E. part of the iſland of Ila.

MAALUM, a town of Bengal; eight miles E. of Toree.

MAAN, John, in *Biography*, a French eccleſiaſtical hiſtorian, was born at Tours, where he probably received the elements of a learned education, being deſigned for the eccleſiaſtical profeſſion: in due time he was admitted doctor by the faculty of the Sorbonne, and became canon and precentor of the church of Tours. He zealouſly devoted his talents and learning to the ſervice of that religion in which he had been brought up. In 1667 he printed at his own houſe a work entitled “ Sancta et Metropolitana Eccleſia Turonenſis, Sacrorum Pontificum ſuorum ornata virtutibus, et ſanctiſſimis Conciliorum Inſtitutis decorata.” This work is highly eſteemed by the French, who repreſent it as replete with erudition and curious reſearches, and as reflecting high honour on the church of Tours and its author. Moreri.

MAANA, in *Geography*, a town of Africa, in the kingdom of Kajaaga, the reſidence of the king, bordering on a branch of the river Senegal, and within a ſhort diſtance of the ruins of Fort St. Joſeph.

MAANINGA, a town of Sweden, in the government of Kuopio; 20 miles N.N.W. of Kuopio.

MAAR, a ſmall iſland in the Eaſt Indian ſea, near the South coaſt of the iſland of Ceram. S. lat. 3° 30′. E. long. 13° 25′.

MAARABAI, a harbour on the W. coaſt of the iſland of Ulietea, in the South Pacific ocean. S. lat. 16° 53′. W. long. 151° 27′.

MAARRA, a town of Aſiatic Turkey, in the government of Aleppo; the reſidence of an aga; 45 miles S.S E. of Aleppo.

MAAS DIRK, in *Biography*, a painter, born at Haerlem in 1656. He at firſt painted ſtill life, after that he ſtudied with and imitated Berchem, but is beſt known by pictures of battles, proceſſions, and cavalcades of horſes, ſomewhat in the ſtyle of Vander Meulen, though not wrought ſo free as the works of that artiſt.

There were two other painters of this name, Arnold van Maas, a diſciple of Teniers, who died young, and Nicholas Maas, who was born at Dort in 1632, and was educated in the ſchool of Rembrandt. He practiſed portrait painting with conſiderable ſucceſs. He lived to the age of 61, and died in 1693.

MAASEYCK, in *Geography*, a town of France, in the department of the Lower Meuſe, and chief place of a canton, in the diſtrict of Ruremonde. The place contains 2205, and the canton 14,704 inhabitants, on a territory of 257½ kiliometres, in 18 communes.

MAASIN, a town on the W. coaſt of the iſland of Leyta. N. lat. 10° 12′. E. long. 124° 49′.

MAASS, in *Commerce*. See MASS.

MAAT, a ſuperficial meaſure of land in Holland, containing 500 ſquare ruthes, of which 600 are equal to a morgen or acre. A ſingle ſquare ruthe contains 169 ſquare feet, each foot being = 121 ſquare inches = 124½ Engliſh inches.

MAATTAN, in *Geography*, a town of Hindooſtan, in Bahar; 34 miles N.N.E. of Durbunga.

MAATZ, NICHOLAS, in *Biography*, an eminent German organ-builder in the ſixteenth century, celebrated by Prætorias, and in Werckmeiſter's organ-gruning. rediv. In 1543 he erected an organ at Stralſund with 43 ſtops, and afterwards was engaged in the ſervice of the king of Denmark.

MAB. See MOAB.

MABA, in *Botany*, is the vernacular name of this genus amongſt the iſlanders of the South Seas. It was firſt deſcribed by Forſter, and afterwards taken up by Linnæus, Schreber, and other authors. Forſt. Gen. 61. Linn. Suppl. 65. Schreb. 678. Mart. Mill. Dict. v. 3. Juſſ. 418. Lamarck Illuſtr. t. 803.—Claſs and order, *Diœcia Triandria*. Nat. Ord. uncertain.

Gen. Ch. Male, *Cal.* Perianth inferior, cloven half way down into three acute, villoſe ſegments. *Cor.* of one petal, tubular, hairy on the outſide; tube cylindrical, longer than the calyx; limb in three, ovate, thickiſh, erect diviſions. *Stam.* Filaments three, thread-ſhaped, ſhorter than the calyx; anthers erect, ovate. *Piſt.* Rudiment globoſe, nearly ſeſſile in the midſt of the flower.—Female, *Cal.* Perianth inferior, permanent, as in the male. *Cor.* and *Piſt.* unknown. *Peric.* Drupa ſuperior, ovate-oblong, of two cells, each containing two oblong, triangular *ſeeds* or *nuts*, ſomewhat convex at their back, flat on both ſides.

Eſſ. Ch. Male, Calyx three-cleſt. Corolla externally hairy; its limb three-cleft. Female, Calyx as in the male. Drupa ſuperior, of two cells.

1. M. *elliptica*. Forſt. Gen. t. 61. Linn. Syſt. Veg. ed. 14. 881. Suppl. 426.—A native of the Friendly Iſlands, more particularly of Tonga Tabu and Namoka.—This is a *ſhrub* whoſe general herbage is extremely ſmooth, its young ſhoots and early leaves alone being hairy. *Leaves* alternate, on ſhort footſtalks, elliptical, veined, very ſmooth. *Stalks* axillary, ſhort, moſtly three-flowered. *Flowers* ſmall, and curious as Linnæus remarks for having the outſide of the calyx and corolla extremely hairy.

Forſter, in his work on eſculent plants, p. 54, mentions another ſpecies, or variety, of this genus, which he calls *Maba major*; the fruit of which is three times as big as that of *elliptica*, the kernels tough and inſipid. The ſame author ſays that the natives eat the nuts of it, and that they were offered for ſale to our people.

MABANOWKA, in *Geography*, a town of Poland, in Volhynia; 12 miles S. of Berdiczow.

MABBY, a kind of wine made from potatoes. It is ſaid to be uſed in Barbadoes.

MABEA, in *Botany*, is derived from the Caribee name of this plant, *Piriri Mabé*. Aublet firſt deſcribed the genus in his *Plantæ Guianenſes*, and ſays it is called *Bois à Calumet* by the French, becauſe the negroes uſe its ſmaller branches as pipes for ſmoaking. Aubl. Guian. 867. Schreb. 641. Willd. Sp. Pl. v. 4. 404. Mart. Mill. Dict. v. 3. Juſſ. 388. Lamarck Illuſtr. t. 773.—Claſs and order, *Monœcia Polyandria*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth inferior, of one leaf, five-toothed, acute. *Cor.* none. *Stam.* Filaments from nine to twelve, inſerted into the bottom of the calyx; anthers roundiſh.—Female, *Cal.* Perianth of one leaf, erect, five-toothed, acute. *Cor.* none. *Piſt.* Germen ſuperior, oblong, ſomewhat triangular, longer than the calyx; ſtyle long; ſtigmas three, thread-ſhaped, revolute. *Peric.* Capſule encloſed in a thick coat, roundiſh, of three lobes and three cells, each cell two-valved, burſting with elaſticity. *Seeds* ſolitary, roundiſh, reddiſh, variegated with grey ſpots.

Eſſ. Ch. Male, Calyx five-toothed. Corolla none. Stamens from nine to twelve inſerted into the calyx.—Female, Calyx five-toothed. Corolla none. Stigmas three. Capſule three-lobed, of three cells. Seeds ſolitary.

Obſ. Juſſieu remarks that in the deſcription of the female flowers of *Mabea* inſtead of "a ſingle ſtyle," it ſhould rather be "ſtyles three, cloſely united or glued into one."

1. M. *Piriri*. Aubl. Guian. t. 334. f. 1.—Leaves ovate-oblong, attenuated at the baſe, pointed.—Found in Guiana and Cayenne, where it flowered and bore fruit in May.—The *trunk* of this plant riſes to about five feet in height, and puts forth numerous, twiggy *branches* very long, ſpreading and entangling themſelves among the neighbouring trees, covered with an aſh-coloured *bark*. *Leaves* alternate, on ſhort footſtalks, entire, green above, whitiſh beneath. *Stipulas* two, long, narrow, deciduous. *Flowers* copious, in long panicles; the males three on a common ſtalk, with two glands and a bractea at the baſe: female flowers beneath the male, ſolitary. Every part of the plant when wounded abounds with a milky ſecretion.

2. M. *Taquari*. Aubl. Guian. t. 334. f. 2.—Leaves oblong, rounded at each end, pointed, ſomewhat heart-ſhaped at the baſe.—Native of Guiana, flowering with the laſt.—This *ſhrub* differs from the laſt in having the *bark* of its trunk and branches of a reddiſh colour. The *leaves* are larger, leſs elongated, and terminated by a ſhort point, curiouſly veined with red underneath. The *fruit* is alſo larger, but in other reſpects it entirely accords with the preceding.

MABER, in *Geography*, a town of Perſia, in Chuſiſtan; 48 miles S.S.W. of Suſter.

MABERIA, a lake of Africa, in the country of *Jinbala*, which ſee; the ſame with the lake of Dibbie, formed by the river Joliba, which runs to the *eaſt*, but miſtaken by d'Anville and Deliſle for the head of the river Senegal, which runs to the *weſt*.

MABEUSE, or MABEUGE, JOHN DE, in *Biography*, one of the early laborious practitioners in the art of painting after the uſe of oil became known in Flanders. He was born at Maubeuge, in Hainault, in 1499.

He was invited by Henry VIII. to England, and employed by him to paint the portraits of his children. By his neat mode of finiſhing, and the ſmoothneſs and high poliſh of his works, he gained in this country, where the art of painting was then almoſt unknown, a very conſiderable reputation, and in conſequence his paintings are not unfrequent among us.

They are known by their dry, ſtiff, and formal manner; both of action in the figures and in the foldings of their draperies, by a total lack of chiaro-ſcuro, and yet poſſeſſing much ingenious taſte in colour; great care in the faces, which always appear to have been portraits; and an almoſt boundleſs labour in the finiſhing; particularly of all the ornamental parts, ſuch as gems, pearls, &c. &c. which he was fond of beſtowing laviſhly.

He is ſaid to have been immoderately addicted to drinking, though he lived to the age of 63.

MABILLON, JOHN, a very learned French Benedictine monk, was born at Pierre-mont, a village belonging to the dioceſe of Rheims, in the year 1632. He was inſtructed in grammar learning by one of his uncles, who afterwards ſent him to the college of Rheims, where he ſoon diſtinguiſhed himſelf by the vivacity of his genius, and an uncommon application to ſtudy. Hence he was taken into the ſeminary of the cathedral, in which the young perſons deſigned for the ſervice of the dioceſe were educated. He continued here three years, and took the habit in an abbey belonging to the Benedictines of the congregation of St. Maur in 1653, and in the following year he made his profeſſion. The higheſt expectations were formed of him; but an inceſſant and almoſt perpetual head-ache rendered him incapable of application, and he was ſent to different places in the country for the recovery of his health. In the year 1660 he was ordained prieſt at Amiens, and as he ſtill laboured under ſo much indiſpoſition, as to render it unfit for him to apply to his ſtudies, he was accordingly employed in ſuch temporal affairs of the congregation as were more adapted to his enfeebled conſtitution. In 1663, in order to reſtrain him from cloſe ſtudies, he was ſent to St. Dennis, and was employed in the low office of exhibiting to ſtrangers the various treaſures and ancient monuments of the abbey. The duties of this ſervile poſt were ill adapted to his mind, and an accident which occurred ſhortly relieved him from the burden which was become almoſt intolerable. He broke a mirror, which it was pretended belonged to the poet Virgil; this ſo enraged his ſuperiors, that they gladly allowed him to make his retreat. His vacant hours he employed in reading the fathers, and in laying up large ſtores of theological, eccleſiaſtical, and critical learning. In 1764 he went to Paris to aſſiſt d'Achery in compiling his "Spicilegium," and took a large ſhare in the buſineſs. The zeal and talents which he manifeſted in this work cauſed him to be appointed to ſuperintend the publication of a complete edition of the works of St. Bernard, which he executed with much correctneſs, judgment, and learning. This work was publiſhed, in 1667, in two folio volumes, and alſo in nine volumes octavo. Immediately after the publication of this great work, he was employed in completing the lives of the ſaints, for which d'Achery and Chantelou had been collecting and digeſting materials. The firſt volume was publiſhed in 1668, under the title of "Acta Sanctorum Ordinis S. Benedicti, &c.;" this was followed at different periods by eight others, of which the laſt was publiſhed in 1702. The work was regarded by the journaliſts of the day, "not as a ſimple collection of memoirs relating to monaſtic hiſtory, but as a valuable compilation of ancient monuments, which being illuſtrated by learned notes, throw much light on the moſt obſcure part of eccleſiaſtical hiſtory. The prefaces themſelves would ſecure to the author an immortal reputation. The manners and uſages of thoſe dark ages are examined with great care, and an hundred important queſtions are diſcuſſed by an exact and ſolid critique." The prefaces were reckoned ſo valuable, that they were publiſhed ſeparately in 1732, in quarto. In 1674 he publiſhed "De Pane Euchariſtico azimo et fermentato Diſſertatio," intended to prove that the Latin church made uſe of leavened bread in the conſecration of the Euchariſt for many ages, and that the uſe of unleavened bread was not introduced till after Photius's ſchiſm. In the following year he publiſhed "Veterum Analectorum, &c.;" but the work which has done moſt honour to the memory of Mabillon appeared in 1681, entitled "De Re diplomatica Libri ſex, &c." So high was the opinion generally entertained of his extraordinary merit, that the celebrated Colbert was deſirous of beſtowing on him a penſion of two thouſand livres, but his unambitious and diſintereſted ſpirit led him to decline that generous offer. In 1682, Colbert engaged him to take a journey into Burgundy, for the purpoſe of examining ſome ancient titles relating to the royal family; after which he ſent him into Germany, to ſearch into the archives and libraries of the ancient abbies in that country, for ſuch documents as might contribute to illuſtrate the hiſtory of France, and that of the church in general, and of the church of France in particular. The reſults of his enquiries into theſe ſubjects were given in the fourth volume of his "Analecta." In 1685, he publiſhed "De Liturgia Gallicana Libri tres, in quibus veteris miſſæ, quæ ante annos mille apud Gallos in uſu erat, forma rituſque eruntur ex antiquis monumentis, &c." In the ſame year Mabillon was ſent at the king's expence into Italy, with the ſame view as he had been formerly ſent into Germany, and was received at Rome with great reſpect; he had free acceſs granted him to all the archives, and to all the libraries, from which he collected a vaſt number of intereſting and important papers, adapted to the deſign of his journey. On his return to France he carried with him a fine collection of books and rare MSS. which he placed in his majeſty's library; and in 1687 he publiſhed an account of his journey, and of the pieces which he had diſcovered, under the title of "Muſæum Italicum, ſeu Collectio veterum Scriptorum ex Bibliothecis Italicis eruta, &c." in two volumes 4to. In 1688, father Mabillon engaged in a diſpute between the Benedictines of Burgundy, and the canons regular, on the ſubject of the precedence of thoſe orders in the ſtates, and, in 1691, he entered into a controverſy with father Rance, abbot of La Trappe, who maintained, that learning and the ſciences were foreign to the monaſtic profeſſion, and who had prohibited the monks almoſt all ſorts of reading, excepting that of the ſcriptures and certain moral treatiſes. In 1698 he publiſhed a work, which involved him in much controverſy and many ſerious difficulties, entitled "Euſebii Romani ad Theophilum Gallum Epiſtola de Cultu ſanctorum ignotorum." It was received by the ſuperſtitious and intereſted, particularly at Rome, in a moſt unfavourable manner. For ſome time it was attacked only by complaints, murmurs, and criticiſms publiſhed in Germany, France, and Italy; but in 1701 it was brought before the congregation of the *Index*, by whom the author would unqueſtionably have been cenſured, if he had not agreed to reprint it with ſuch alterations, emendations, and omiſſions as ſhould be ſuggeſted to him. In the ſame year Mabillon was choſen honorary member of the Academy of Inſcriptions, and publiſhed the firſt volume of the laſt great work to which he devoted his labours, entitled "Annales Ordinis S. Benedicti in quibus non modo res Monaſticæ, ſed etiam Eccleſiaſticæ Hiſtoricæ non minima pars continetur." The ſecond, third, and fourth volumes ſucceeded, and the fifth was compoſed by Mabillon, but not publiſhed till after his deceaſe. Mabillon died in December 1707, ſoon after he had completed his ſeventy-fifth year. In ſpeaking of his great merit, Dupin ſays, "The voice of the public, and the general eſteem of all the learned, are a much better commendation of him than any thing which we can ſay. His profound learning appears from his works; his modeſty, humility, meekneſs, and piety, are no leſs known to thoſe who have had the leaſt converſation with him. His ſtyle is maſculine, pure, clear, and methodical, without affectation or ſuperfluous ornaments, and ſuitable to the ſubjects of which he has treated." In 1724 the poſthumous works of our author were publiſhed in three volumes 4to. by Thuillier. Moreri. Dupin.

MABLY, BENNET DE, abbè, an eminent political writer, was born at Grenoble in 1709. He was brother of the abbè Condillac, whom he reſembled in acuteneſs and penetration. He devoted himſelf to the ſtudy of literature, and died at Paris in 1785. His principal works are "Obſervations on the Greeks;" "Obſervations on the Romans;" "Parallel of the Romans and French;" "Obſervations on the Hiſtory of France;" "Diſcourſes on Hiſtory." All the writings of this author diſplay deep thinking, ſound moral principles, and a great regard for the good of mankind. He is, however, thought to be too much of a panegyriſt of the ancients, and too fond of applying their political maxims to the very different circumſtances of modern ſtates. The work of his old age, entitled "Sur les Conſtitutions des Etats Unis de l'Amerique," gave offence by ſome ſentiments adverſe to civil liberty and religious toleration.

MABOUJAS, the *Devil-lizard*, in *Zoology*, a ſpecies of American lizard, ſo called from its uglineſs and diſagreeable aſpect. It grows to ſix or ſeven inches long, and to the thickneſs of a thumb, and is found in the trunks of rotten trees, and in marſhy places, where the ſun-beams ſeldom reach; it is all over of a gloſſy black colour, and looks as if ſmeared over with oil.

MABOUL, JAMES, in *Biography*, an eminent French prelate, diſtinguiſhed for his pulpit eloquence, and particularly for his orations delivered in praiſe of deceaſed perſons of merit, was deſcended from a family of high rank. He obtained conſiderable eminence in the church, and was employed by the duke of Orleans, the regent, in a fruitleſs attempt to reconcile the hoſtile parties who were contending about the bull *Unigenitus*. His funeral diſcourſes were publiſhed in one volume 12mo, in 1749: they are ſaid to be diſtinguiſhed by that ſweetneſs of ſtyle, that nobleneſs of ſentiment, that elevation, that unction, and that touching ſimplicity, which are the characteriſtics of a good mind, and of true genius. Moreri.

MABRA, in *Geography*, a town of Algiers, in the gulf of Bona; 10 miles W. of Bona.

MAC, an Iriſh word ſignifying *ſon*; frequently prefixed to ſurnames; as *Mac*donald, for Donald's ſon; *Mac*laurin, for Laurence's ſon, &c.

MACA, in *Geography*, a town of Africa, in Hoval; 20 miles from the mouth of the Senegal.

MACABALAR BAY, a bay on the N.W. coaſt of the iſland of Mindanao.

MACABRA, a town of Africa, in Sennaar; 40 miles S.S.W. of Meroe.

MACACO, in *Zoology*. See LEMUR *Macaco*.

MACADRA, in *Geography*, a town of Arabia, in Yemen; 32 miles S. of Chamir.

MACÆ, in *Ancient Geography*, a people of Africa, E. of the Naſamones and near the ſea. Some have ſuppoſed they are the ſame with thoſe called Syrtites by Ptolemy, becauſe they inhabited towards the Great Syrtis. The Cinyps watered their country, and hence Silius Italicus denominates them Cinyphii Macæ.

MACAENS *de Caminho*, in *Geography*, a town of Portugal, in Eſtremadura; 33 miles S.S.E. of Coimbra.

MACAIRE, ST., a town of France, in the department of the Gironde, and chief place of a canton, in the diſtrict of La Reole. The place contains 1483, and the canton 9980 inhabitants, on a territory of 102½ kiliometres, in 15 communes.

MACALLESTER'S BAY, a bay on the E. coaſt of the iſland of Mull. N. lat. 56° 30′. W. long. 5° 45′.

MACALUNGO, a town of Africa, in Mozambique. S. lat. 17°. E. long. 39°.

MACAM, *Indian apple*, in *Natural Hiſtory*, the name of a common Eaſt Indian fruit: it is of a round ſhape, and about the ſize of our common wild crabs which grow in the hedges: inſtead of the ſeveral ſmall ſeeds, which our crabs and apples contain, this fruit has only one hard kernel; it is of an acid taſte, and of a raw and not very agreeable ſmell; the tree which produces this fruit does not grow to any height: it reſembles the quince tree in its leaves, except that they have a yellowiſh caſt. Mem. Acad. Par. 1699.

MACAN, in *Geography*, a town of Perſia, in Khoraſan; 60 miles W. of Meru-Shahigian.

MACANAO, a ſmall iſland in the Caribbean ſea, near the W. coaſt of Margarita. N. lat. 11°. W. long. 64° 40′.

MACANEA, in *Botany*, is a name adopted by Juſſieu for the *Macahanea* of Aublet deſcribed in the ſupplement of his Plants of Guiana, and figured in t. 371 of that work. Neither of thoſe authors had ſeen any of the parts of fructification except the *berry* and *ſeeds* which are thus deſcribed. *Peric.* Berry large, pear-ſhaped, of one cell, pulpy withinſide; its outſide leathery, ſprinkled with red ſpots. *Seeds* from four to ſix, ovate, leathery, covered with a membrane and lying in a white pulp. Aublet, who found this plant in fruit in June, calls it by the ſpecific name of *guianenſis*, with the following deſcription.—*Shrub* putting forth numerous *branches*, twiſting themſelves about the neighbouring trees. *Leaves* oppoſite, on footſtalks, toothed, ovate, acute, ſmooth. *Fruit* axillary, in cluſters.—From the imperfect ſtate in which *Macanea* is known, we cannot pronounce to what claſs it belongs. Juſſieu ranks it amongſt the Natural Order of *Guttiferæ*, and ſays that it is nearly allied to *Mammea* and *Singana*.

MACANNA, in *Geography*, a kingdom of Africa, S. of Bambouk.

MACAO, a town of Portugal, in Eſtremadura; 12 miles N.E. of Abantes.

MACAO.

MACAO, a ſea-port town of China, in the province of Quang-tong, ſituated at the mouth of the Tigris, in the entrance of the bay of Canton, and built on a peninſula, or rather a ſmall iſland, becauſe it is ſeparated from the land by a river, where the ebbing and flowing of the ſea are ſenſibly felt. This tongue of land is joined to the reſt of the iſland only by a ſmall neck, about 100 yards acroſs. The Portugueſe obtained this port from the emperor Camhy, as a reward for the aſſiſtance they gave to the Chineſe in deſtroying the pirates, who from the iſlands in the vicinity of Canton infeſted the ſeas and ravaged all the coaſts of China. Some writers pretend, that this city had no inhabitants but pirates when the Portugueſe formed an eſtabliſhment in it; and that they were only permitted to build huts covered with ſtraw. However this be, their whole extent of territory, bounded by a wall, is not more than eight miles in circumference. In this ſmall ſpot, the Portugueſe carried on, for a long time, almoſt excluſively, a conſiderable traffic with the Chineſe empire, and with other countries in Aſia, particularly Japan, Tonquin, Cochinchina, and Siam. But by the luxury occaſioned by increaſe of wealth and the injurious oppreſſion of the Chineſe, the enterpriſing ſpirit of the Portugueſe declined, and the inhabitants of Macao became enervated by a tropical climate. Their trade to Japan failed; their other ſpeculations became precarious; and this once proſperous ſettlement is now very much reduced. The houſes at Macao are built after the European manner, but they are low, and make little ſhow. Here are 13 churches and chapels, and 50 prieſts, to miniſter to the devotion of between four and five thouſand laity. Of the two pagan temples at Macao, belonging to the Chineſe, one is curiouſly ſituated among a confuſed heap of immenſe maſſes of granite. This temple is compriſed of three ſeparate buildings one over the other; the only approach to which is by a winding flight of ſteps hewn out of the ſolid rock. The cave of Camoens, ſituated a little above the loftieſt eminence in the town, was conſtructed, probably, in the ſame manner as the temple above deſcribed, by bringing together a vaſt number of rocks. This cave, from a tradition current in the ſettlement, belonged to Camoens, a Portugueſe poet, who reſided a conſiderable time at Macao, and in which cave, it is ſaid, he wrote the celebrated poem of the Luſiad. The whole population of Macao, according to the ſtatement of La Perouſe, may be computed at 20,000, of whom 100 are Portugueſe by birth, 2000 metis, or half Indians and half Portugueſe, with as many Caffre ſlaves, their domeſtics. The reſt are Chineſe, who employ themſelves in commerce and different trades, by which they lay the Portugueſe under contribution to their induſtry. Theſe laſt, though almoſt all Mulattoes, would think themſelves diſgraced, if they ſupported their families by exerciſing any mechanic art, though their pride is not above continually ſoliciting charity, with importunity, from every one that paſſes by them.

The road-ſtead of Macao is ſufficiently ſpacious to contain 60 gun-ſhips at the entrance of Typa; and in its harbour, which is below the town, and communicates with the river up to the eaſtward, ſhips of ſeven or eight hundred tons, with half their lading. The mouth of this harbour is defended by a fortreſs of two batteries, which muſt be kept within piſtol-ſhot in entering. Three ſmall forts, two of which are mounted with twelve guns, and the third with ſix, protect the ſouth ſide of the town from every attempt of the Chineſe. Theſe fortifications, which are in the worſt poſſible ſtate, would be far from formidable to Europeans, but they may eaſily overawe all the maritime forces of the Chineſe. A mountain alſo commands the road, where a detachment of troops could hold out a very long ſiege. The Portugueſe of Macao, more devout than warlike, have built a church on the ruins of a fort, which covered this mountain, forming, at that time, an impregnable poſt. The ſide next the land is defended by two fortreſſes, one of which is mounted with 40 guns, and capable of containing a garriſon of 1000 men. It is provided with a ciſtern, two ſprings of running water, and caſemates for laying up warlike ammunition and proviſions. The other, which mounts 30 guns, cannot receive above 300 men, and has a very abundant ſpring that never fails. Theſe two citadels command the whole country. The Portugueſe frontiers extend nearly a league from the town, and are bounded by a wall guarded by a mandarin and a few ſoldiers. This mandarin is the true governor of Macao, whom all the Chineſe obey, though he is not allowed to ſleep within theſe limits. But he may examine all the fortifications, inſpect the cuſtom-houſes, &c.; and on theſe occaſions the Portugueſe are obliged to give him a ſalute of five guns: but no European can make a ſingle ſtep on the Chineſe territory, beyond the wall, which would ſubject him either to impriſonment or a heavy contribution. The palace of the Chineſe mandarin is in the middle of the city; and the Portugueſe are conſtrained to pay a tribute of 100,000 ducats for the liberty of chooſing their own magiſtrates, exerciſing their religion, and living according to their own laws. The viceroy of Goa nominates to all civil and military offices at Macao, and appoints the governor and all the ſenators, who participate in the civil authority. He has lately fixed the garriſon at 180 Indian ſeapoys, and 120 militia-men, whoſe ſervice conſiſts in patroles at night. The ſoldiers are armed with ſticks, and the officer alone has the privilege of wearing a ſword; though he can on no occaſion employ it againſt a Chineſe. The ſenate of Macao is compoſed of the governor, who is preſident, and three "verendores," who are the auditors of the city finances. The revenue conſiſts of the duty laid on merchandize, which can only be imported in Portugueſe veſſels. If Macao were made a free port, and had a garriſon capable of defending commercial property, when depoſited there, the revenue of their cuſtom-houſe would be doubled, and would be adequate to all the expences of the government. But a trifling intereſt pertaining to the viceroy of Goa, from ſelling Portugueſe commiſſions to merchants of various nations who carry on a coaſting trade in the Eaſt Indies, and preſents from ſhip-owners to the ſenate of Macao, raiſe an inſurmountable obſtacle to the eſtabliſhment of a free trade; though this would render Macao one of the moſt flouriſhing cities of Aſia, and inconceivably ſuperior to Goa, whoſe utility to its mother-country will never be conſiderable. Beſides the "verendores," there are two judges of orphans, whoſe department includes the adminiſtration of the property of minors, the execution of wills, the nomination of tutors and guardians, and every thing relating to ſucceſſions. From their deciſion an appeal lies to that of Goa. Other civil or criminal cauſes are alſo cognizable, in the firſt inſtance, by two ſenators, who are nominated as judges. A treaſurer receives the produce of the cuſtoms; and his diſburſements, above a certain amount, muſt be ſanctioned by an order of the viceroy of Goa. The moſt important magiſtracy is that of the procurator of the city, which is an intermediate office between the Portugueſe government and that of China. This office is for life; that of the governor is triennial; and the other magiſtrates are replaced every year. An appeal lies to Goa from all the deciſions of the ſenate, which their notorious incapacity renders indiſpenſible. This city is rendered pleaſant in appearance by the fine houſes occupied by the ſupercargoes of the different companies, obliged to winter here; and their ſociety enlivens the place. N. lat. 22° 12′ 40″. E. long. 109°. Groſier. De la Perouſe.

In the folio volume annexed to ſir George Staunton's "Authentic Account of an Embaſſy from the King of Great Britain to the Emperor of China," there is a plan of the city and harbour of Macao; containing references to all the forts, colleges, convents, and other public buildings, and places of note; and alſo the depth of water, and nature of the ground, in every part of the inner harbour, as well as in the ſpace between the peninſula and the northern entrance into the Typa; taken from an accurate ſurvey made by a gentleman long reſident on the ſpot.

Macao, *New*, a ſea-port town of Tonquin, at the bottom of a large bay, full of iſlands. N. lat. 21° 30′. E. long. 107°.

Macao, *Macaw*, in *Ornithology*. See Psittacus *Macao*.

MACAPA, in *Geography*, a town of South America, in the government of Peru, on the north bank of the river of the Amazons, nearly on the equinoctial line. W. long. 52°.

MACAQUO, in *Zoology*, the name of a large ſpecies of monkey called by Mr. Ray *cercopithecus Angolenſis major*, the great Angola monkey. See Simia *Cynomulgus*.

They have another ſpecies of this kind alſo about Angola, which may be called the black macaquo. Its only colour is black; but on many parts of the back and ſides, there is a greyiſh caſt among it: this has a tail of remarkable length, being more than two feet long. See Simia.

MACARAGUA, in *Geography*, a town of the iſland of Cuba; 45 miles N.W. of Havanna.

MACARAUX, in *Ornithology*. See Alca *Arctica*.

MACARIA, in *Geography*, a town on the weſt coaſt of the iſland of Metelin; 10 miles W. of Metelin.

MACARIANS, in *Eccleſiaſtical Hiſtory*, the followers of Macarius, an Egyptian monk, who was diſtinguiſhed, towards the cloſe of the fourth century, for his ſanctity and virtue. In his writings there are ſome ſuperſtitious tenets, and alſo certain opinions that ſeem tainted with Origeniſm. The name has been alſo applied to thoſe who adopted the ſentiments of Macarius, a native of Ireland, who, about the cloſe of the ninth century, propagated in France the error afterwards maintained by Averrhoes, that one individual intelligence or ſoul performed the ſpiritual and rational functions in all the human race.

MACARIUS, St., in *Biography*, a famous anchoret of the fourth century, was a native of Alexandria. He ſpent ſixty years in a monaſtery, and is ſaid to have been a diſciple of St. Anthony, the firſt inſtitutor of a monaſtic life. He died in the year 391, when he was about ninety years of age. Fifty homilies have been attributed to him: theſe were firſt publiſhed in Greek, at Paris, in 1559. He is ſuppoſed to have been the author of many ſmaller tracts, "On Prayer," "Watching the Heart," "Perfection of the Mind," &c. The beſt edition of his pieces is that publiſhed at Leipſic in 1698. Moreri.

Macarius, *St.*, *the Younger*, a celebrated monk, likewiſe a native of Alexandria, who had 5000 monks under his direction. Of his ſanctity, virtues, and abſtinence, wonders are related by Palladius. He was baniſhed by the Arians to an iſland inhabited by heathens, whom he converted to, what was called at that period, Chriſtianity. He died about the year 404, when he was nearly 100 years of age. To him have been attributed "Rules for Monks," in 30 chapters, firſt publiſhed in Latin by Peter Roverius the Jeſuit. Moreri.

Macarius, *St.*, *Deſert of*, in *Geography*, a deſert on the weſt part of Egypt, denominated in honour of a ſaint, to whoſe honour a convent of monks has been founded, anciently called "Nitria." The convent is about 50 miles N.N.W. of Cairo.

MACARON, the name of a ſort of vermicelli, a paſte made of flour and water, and formed in the ſhape of the barrel of a large quill, or the guts of ſmall fowls.

MACARONIC, or Macaronian, a kind of burleſque poetry; conſiſting of a jumble of words of different languages, with words of the vulgar tongue latinized, and Latin words modernized.

Macarone, among the Italians, as has been obſerved by Cælius Rhodiginus, ſignifies a coarſe clowniſh man; and becauſe this kind of poetry, being patched out of ſeveral languages, and full of extravagant words, is not ſo polite and ſmooth as thoſe of Virgil, &c. the Italians, among whom it had its riſe, gave it the name of Macaronian or Macaronic poetry. Others chooſe to derive it *a Macaronibus*, from Macaroons, a kind of confection made of meal not bolted, ſweet almonds, ſugar, and the whites of eggs; accounted a great dainty among the country people in Italy; which, from their being compoſed of various ingredients, occaſioned this kind of poetry, which conſiſts of Latin, Italian, Spaniſh, French, Engliſh, &c. to be called by their name.

Theoph. Folingius, a Benedictine monk of Mantua, was the firſt who invented, or at leaſt cultivated, this kind of verſe: for though we have a Macaronea Ariminenſis in a very old letter, beginning, "Eſt author Typhis Leonicus atque Paranſus;" yet it ſeems to have been the work of Guarinus Capellus Sarſinas, who, in the year 1256, printed ſix books of Macaronic poetry, in Cabrinum Gagamonæ Regem: but as both thoſe came out after the firſt edition of Folingius, which was publiſhed under the name of Merlinus Coccajus in 1520, ſo they were likewiſe much inferior to his in the ſtyle, invention, and epiſodes, wherewith he has enriched the hiſtory of Baldus; which makes the ſubject of his poem. The famous Rabelais firſt transferred the Macaronic ſtyle out of the Italian verſe into French proſe, and on the model thereof formed ſome of the beſt things in his Pantagruel.

We have ſcarce any thing in Engliſh in the Macaronian way, except ſome little looſe pieces collected in Camden's Remains; which is no diſcredit to our authors: for one may ſay of ſuch pieces in general,

> "Turpe eſt difficiles habere nugas,
> Et ſtultus labor eſt ineptiarum."

But the Germans and Netherlanders have had their Macaronic poets; witneſs the "Certamen Catholicum cum Calviniſtis" of one Martinius Hamconius Friſius, which contains about twelve hundred verſes, all the words whereof begin with the letter *C*.

MACAROON. See Macaronic.

MACAROWA, in *Geography*, a town of Poland, in the palatinate of Kiev; 24 miles N.W. of Kiev.

MACARSCA, a town of Dalmatia, and ſee of a biſhop, ſuffragan of Spalatro; ſituated in a territory, formerly pleaſant and fertile, and convenient for commerce, but more lately deteriorated, and ſuppoſed to have ariſen out of the ruins of the ancient Ratanaum or Retinum; 36 miles E.S.E. of Spalatro.

MACARTNEY, George, *Earl of*, in *Biography*, the ſon of George Macartney, eſq. of Auchinleck in Scotland, was born in Ireland in 1737, and was educated as a fellow-commoner in Trinity-college, Dublin, where he took his degrees in 1759. Shortly after this, he travelled with the ſons of the late lord Holland. This, perhaps, was his introduction to court. His education had been liberal, and he had improved the advantages which he poſſeſſed from a fortunate train of circumſtances. He had an aſpiring mind, and excellent talents, and was ambitious of ſome public employment. His own wiſhes were ſeconded by the zeal of his friends, and he was, in 1764, appointed envoy extraordinary to the empreſs of Ruſſia. The object of this miſſion, and of the appointment of this young man, was the great importance of the commercial and political relations between Great Britain and the empire of Ruſſia; and it was neceſſary, at that period, to counteract the influence of France at the Ruſſian court. The character and policy of that court required to be particularly ſtudied: and hence the embaſſy from this country included an office that required much penetration, vigilance, and diſcretion, as well as inſinuating manners, and an agreeable addreſs. Theſe qualifications were thought, by the moſt diſcerning judges, to be united in Mr. Macartney. The principal buſineſs of his miſſion was to negociate a commercial treaty, for the benefit of the Ruſſia merchants trading to Ruſſia. Of the intereſts of the Ruſſian trade he was well informed. His addreſs ſurmounted every difficulty of acceſs to the empreſs and her miniſters: he knew how to ſeize the proper moment for negociation; and he had coolneſs and patience to conquer every obſtacle which might be oppoſed to his views by the artifices of others. He in a ſhort time procured the Ruſſian court to agree to a treaty ſatisfactory to the wiſhes of the Britiſh merchants at Peterſburgh, and ſuitable to the inſtructions which he had received at home. An addreſs from the merchants of the Britiſh factory at St. Peterſburgh; the honour of the knighthood of the Poliſh order of the White Eagle, conferred by a monarch who was himſelf at once a man of faſhion, taſte, and pleaſure, and a man of political talents; and the elevation to the character of ambaſſador extraordinary and plenipotentiary from the Britiſh court, in which he finally concluded the treaty of commerce, were among the teſtimonies of approbation and reſpect which ſir George Macartney obtained by his conduct in this diplomatic miſſion to the north. Thus ſucceſsful and diſtinguiſhed, he returned to the Britiſh court about the cloſe of the year 1767. Early in the following year he married lady Jane Stuart, ſecond daughter of the earl of Bute. By this marriage he had contracted a relationſhip to ſir James Lowther, afterwards the earl of Lonſdale; and by that gentleman's intereſt with, or influence over, the electors, he was choſen, in the ſame year, one of the repreſentatives of the borough of Cockermouth; after which we find him choſen a repreſentative in the Iriſh parliament for the borough of Armagh. In 1769 ſir George was nominated principal ſecretary to the late marquis Townſhend, in the high office which he then filled of lord lieutenant of Ireland. In 1772 he was nominated by his ſovereign knight of the Bath, and in 1775 went out as governor of Grenada and Tobago. He continued there till 1779, when, on the capture of thoſe iſlands by the French, he was taken priſoner, and ſent to France. In 1776 he had been made an Iriſh peer by the title of lord Macartney, baron Liſſanoure, in the county of Antrim. As the loſs of Grenada had not occurred from any miſconduct in him, but the defence of it had indeed been ſignalized by the moſt illuſtrious diſplay of all his great qualities, he met with a very gracious reception from his ſovereign on his return. In 1780 he was choſen to repreſent Beeralſtone in the Britiſh parliament; and in the following winter he was appointed governor and reſident of Fort St. George at Madras, in the Eaſt Indies: and he went without delay to diſcharge the functions of his appointment, where his conduct obtained ſuch univerſal approbation, that, in 1785, he was appointed to the high office of governor-general of Bengal; which honour, however, after due conſideration, he choſe to decline, and returned to England. In 1786 he received a flattering teſtimony of reſpect from the court of directors of the Eaſt India company, who granted him an annuity for his life of 1500*l. per annum*, which was beſtowed as a reward for the important ſervices which this illuſtrious nobleman had rendered to the company. The ſame year he fought a duel with general Stuart, whom he had ſuperſeded in India. In 1788 he took his ſeat for the firſt time in the Iriſh houſe of peers; and about the ſame time was appointed one of the truſtees of the linen manufacture for the province of Ulſter, and alſo cuſtos rotulorum for the county of Antrim. He was promoted likewiſe to the command of a regiment of dragoons in the Iriſh militia. In 1792 he was ſelected as the fitteſt perſon for ambaſſador from the king of Great Britain to the emperor of China. He was on the ſame day nominated a privy-counſellor; and in a few weeks he was raiſed to the rank of an Iriſh viſcount, under the title of viſcount Dervock, in the county of Antrim. He now proceeded, without delay, on his embaſſy, attended by ſir George Staunton as his ſecretary, and a great train of followers and ſervants. A ſhip of war, under the command of ſir Eraſmus Gower, was, with ſmaller veſſels, aſſigned for his voyage. Many rich preſents were ſent from the Britiſh to the Chineſe ſovereign. He arrived in ſafety in the Indian ſeas; and when his approach was announced at the Chineſe court, the emperor and his miniſter agreed, though not without ſome heſitation, to receive the ambaſſadors and preſents. In his approach to Pekin, the northern capital of the empire, his lordſhip was obliged to direct his voyage round the South ſea coaſt of China, by a tract hitherto almoſt unknown to European navigators. The opportunity of exploring that tract was regarded as almoſt ſufficient to compenſate for all the difficulties and expence of the embaſſy. As ſoon as he landed, mandarins of the higheſt rank were appointed to conduct him to the imperial court. His preſents were accepted, and he, with all his train, were treated in a hoſpitable, and even ſumptuous manner: but the main object of the miſſion was completely fruſtrated, *viz.* to obtain permiſſion for the permanent reſidence of a Britiſh ambaſſador at the court of China. This was abſolutely refuſed, and lord Macartney and his train returned over land. His lordſhip entered Canton in December 1793; and from thence he proceeded to Macao; and in March 1794, he ſailed from that port to Europe. He arrived in England in the following September, after an abſence of almoſt two years. On his return he was created an Iriſh earl; and in 1796 he was farther advanced to the dignity of a Britiſh peer, by the title of baron Macartney of Parkhurſt, in Suſſex. After this, he was called to the adminiſtration. In this high ſtation, as in the other offices which he filled, lord Macartney diſplayed qualities which are honourable to his talents as a ſtateſman, and his feelings as a man. His lordſhip died on the 31ſt of March 1806. Monthly and European Magazines. Britiſh and Iriſh Peerages.

MACAS, in *Geography*, a province of the viceroyalty of New Granada, in South America, bounded on the eaſt by the government of Maynas, ſouth by that of Bracamoros and Yaguarſongo, and on the weſt the eaſt Cordillera of the Andes divides it from the juriſdiction of Rio Bamba and Cuença. Its chief town bears the ſplendid title of the city of Macas; and this is better known than its proper ancient name of Sevilla del Oro. It lies in S. lat. 2° 30′, 40′ E. of Quito. Its houſes, which do not exceed 130, are built of timber, and thatched. Its inhabitants are reckoned at about 12,000, who, as well as thoſe of the whole diſtrict, are generally Meſtizos with Spaniards. The other towns belonging to this juriſdiction are San Miguel de Narbaes, Barahonas, Yuquipa, Juan Lopez, Zuna, Payra, Copueno, and Aguayos. The ſpiritual government of all theſe towns is lodged with two prieſts; one of whom, reſiding in the city, has the care of the four firſt; and to the latter, who lives at Zuna, belongs that town and the three others. At the conqueſt, and for ſome time after, this country was very populous, and, in honour of the great riches drawn from its capital, was diſtinguiſhed by the name of Sevilla del Oro; but at preſent only the memory of its former opulence remains. The proximity of Macas to the Cordillera of the Andes occaſions a ſenſible difference betwixt its temperature and that of Quixos adjoining to it. The winter here begins in April, and laſts till September, which is the time of ſummer betwixt the Cordilleras; and at Macas the fine ſeaſon is in September, and is the more delightful on account of the winds, which are then moſtly northward. In grains and other products, which require a hot and moiſt temperature, the country is very fruitful; but one of the chief occupations of the country people here is the culture of tobacco, which, being of an excellent kind, is exported in rolls all over Peru. Sugar-canes alſo thrive well, and likewiſe cotton. Among the infinite variety of trees, which crowd the woods of this country, one of the moſt remarkable is the ſtorax, diſtinguiſhed by the exquiſite fragrancy of its gum. The territory belonging to Macas alſo produces cinnamon trees of an excellent quality. Great quantities of copal are brought from Macas, and alſo wild wax of little value, becauſe it never indurates, and the ſmell of it, when made into candles, and theſe are lighted, is very ſtrong and diſagreeable. Juan and de Ulloa's Voyage to South America, vol. i.

Macas, a town of Africa, in the kingdom of Hoval, near the mouth of the Senegal.—Alſo, a river of Portugal, which runs into the Atlantic, N. lat. 38° 51′. W. long. 9° 25′.

MACASIN, a town on the S. coaſt of the iſland of Midnanao. N. lat. 7° 45′. E. long. 124° 16′.

MACASSAR, or **Macasser**, a ſea-port town of the iſland of Celebes, and the principal ſettlement of the Dutch in this iſland. It gives name to one of the two great kingdoms into which the iſland is divided, and the iſland itſelf is ſometimes diſtinguiſhed by this appellation. Under the article Celebes, the reader will find a particular account of it. Of the town captain Carteret, who viſited it in 1768, gives the following account. (See Hawkeſworth's Voyages, vol. i.) It is built upon a kind of point or neck of land, and is watered by a river or two, which either run through or very near it. It ſeems to be large, and there is water for a ſhip to come within half cannon-ſhot of the walls: the country about it is level, and has a moſt beautiful appearance: it abounds with plantations and groves of cocoa-nut trees, with a great number of houſes interſperſed, by which it appears to abound with people. At a diſtance inland, the country riſes into hills of a great height, and becomes rude and mountainous. The town lies in S. lat. 5° 1′, or 5° 12′. E. long. by account, 117° 28′.

Macassar, *Straight of*, a paſſage between the iſlands of Borneo and Celebes. There is in this paſſage a remarkable point, called by captain Carteret "Hummock Point," but in the French charts denominated "Stroomen Point." N. lat. 1° 20′. E. long. 121° 39′. This point is a good mark for thoſe to know the paſſage that fall in with the land coming from the eaſtward, who, if poſſible, ſhould always make this ſide of the paſſage. To the ſouthward of this point there is a deep bay, full of iſlands and rocks, which appeared to Carteret to be very dangerous. Juſt off the point there are two rocks, which, though they are above water, cannot be ſeen from a ſhip till ſhe is cloſe to the land. To the eaſtward of this point, cloſe to the ſhore, are two iſlands, one of them very flat, long, and even, and the other ſwelling into a hill, but both were covered with trees. Hawkſ. Voy. vol. i.

Macassar *Poiſon*, in *Natural Hiſtory*, called *ippo*, or *upas*, in the Macaſſar and Malayan tongue, is the gum of a certain tree, ſhining, brittle, black, and every way like ſtone-pitch, growing in the iſland of Celebes, in the South Seas; with which all the natives arm themſelves in travel, having a long hollow trunk of a hard red-wood like Brazil, accurately bored, and at one end is fixed a large lance-blade of iron. Then they make a ſmall arrow very ſtraight, and ſomewhat bigger than a large wheaten ſtraw: at one end they fix it into a round piece of white, light, ſoft wood, like cork, about the length of the little finger, juſt fit for the bore of the trunk, to paſs clear by the force of one's breath, and to fill it ſo exactly, that the air may not paſs by, but againſt it, in order to carry it with the greater force. At the other end they fix it either in a ſmall fiſh-tooth for that purpoſe, or make a blade of wood of the bigneſs of the point of a lancet, about three-quarters of an inch long, and making a little notch at the end of the arrow, they ſtrike it firm therein, which they anoint with poiſon. The poiſonous gum, when gathered, is put into hollow bamboos or canes, ſtopped up very cloſe, and thus brought to Macaſſar. When they fit it for uſe, they take a piece of ſmooth turtle ſhell, and a ſtick cut flat and ſmooth at the end: then they take green galangal root, grate it, and with the addition of a little fair water, preſs the juice into a clean china diſh: then with a knife, ſcraping a little of the poiſon upon the ſhell, dip the end of the ſtick in the fore-mentioned liquor, and with this diſſolve the poiſon, to the conſiſtence of a ſyrup: when this is done, they anoint the fiſh-tooth or wooden blade with the ſame ſtick and lay them in the ſun, ſo that it may be baked hard. The pointed arrows thus prepared are put in hollow bamboos, cloſe ſhut, and in this ſtate they retain their virtue for a month. Birch's Hiſt. of the Royal Society, vol. ii. p. 44.

Rumphius, a reſpectable author in Natural Hiſtory, of the 17th century, mentions a tree growing at Macaſſar, to which he gives the name of *Toxicaria;* and relates, that not only the red reſin contained a deadly poiſon, but that the drops falling from the leaves upon the men employed in collecting this reſin from the trunk, produced, unleſs they took particular care in covering their bodies, ſwellings and much illneſs; and that the exhalations from the tree were fatal to ſome ſmall birds attempting to perch upon its branches. But many of the particulars of this account, though far removed from that of the ſuppoſed Upas, or poiſon-tree of Java by Foerſch, who had been for ſome time a ſurgeon in Java, and who had travelled into ſome parts of the interior of the country, are given not upon the author's own obſervation, and may have been exaggerated. Foerſch's relation of a tree ſo venomous as to be deſtructive, by its exhalations, at the diſtance of ſome miles, is compared at Java to the fictions of Baron Munchauſen, or as a bold attempt to impoſe upon the credulity of perſons at a diſtance. Foerſch's account, however, was admitted in a note to Darwin's celebrated poem of the Botanic Garden, and this circumſtance led Dr. Gillan, and others belonging to Macartney's Embaſſy to China, to make inquiries into the fact: and the reſult was as we have above ſtated it. It is, indeed, a common opinion at Batavia, that there exiſts, in that country, a vegetable poiſon, which, rubbed on the daggers of the Javaneſe, renders the ſlighteſt wounds incurable; though ſome European practitioners have of late aſſerted that they had cured perſons ſtabbed by thoſe weapons; but not without the precaution of keeping the wound long open, and procuring a ſuppuration. One of the keepers of the medical garden at Batavia, aſſured Dr. Gillan, that a tree diſtilling a poiſonous juice was in that collection; but that its qualities were kept ſecret from moſt people in the ſettlement, leſt the knowledge of them ſhould find its way to the ſlaves, who might be tempted to make an ill uſe of it. Staunton's Embaſſy, vol. i. p. 273. See POISON.

MACATES, in *Geography*, a town of South America, in the province of Carthagena; 25 miles S.E. of Carthagena.

MACAULAY, CATHARINE, in *Biography*, a diſtinguiſhed writer in hiſtory and politics, the youngeſt daughter of John Sawbridge, eſq. of Ollantigh, in the county of Kent, was born in the year 1733. She appears to have imbibed, from a very early period, a zealous attachment to the principles of liberty, which the hiſtorians of Greece and Rome had infuſed into her heart. The impreſſions made upon her mind in her youth were never obliterated. In 1760 ſhe married Dr. George Macaulay, a phyſician of London. Soon after this, ſhe commenced her career in literature. and in 1763 publiſhed the firſt volume, in quarto, of her "Hiſtory of England, from the acceſſion of James I. to that of the Brunſwick Line." This work was completed in eight volumes in 1783: it was read with great avidity at the period of its publication, but has ſince fallen into ſo much diſrepute, as ſcarcely ever to be enquired after. It was written in the pure ſpirit of republicaniſm, but it unqueſtionably had too much of party ſpirit in it to admit of that partiality which ought to be the characteriſtic of true hiſtory. While in the height of her fame, Mrs. Macaulay excited the admiration of Dr. Wilſon, rector of St. Stephen's, Wallbrook, who conferred on her the unprecedented honour of placing her ſtatue, while living, in the chancel of his church, which his ſucceſſor thought himſelf juſtified in removing. Having been left a widow, Mrs. Macaulay, in 1778, married Mr. Graham, a ſtep, in which the great diſparity of years expoſed her to ſome ridicule. In 1785 ſhe went to America, for the purpoſe of viſiting the illuſtrious Waſhington, with whom ſhe had before maintained a correſpondence. She died in the year 1791. Her works, beſides the hiſtory already referred to, which may be regarded as the principal, are "Remarks on Hobbes's Rudiments of Government and Society;" "Looſe Remarks on ſome of Mr. Hobbes's Poſitions;" the latter being an enlarged edition of the former: the object of theſe is to ſhew the ſuperiority of a republican to a monarchical form of government. In 1770, Mrs. Macaulay wrote a reply to Mr. Burke's celebrated pamphlet entitled "Thoughts on the Cauſes of the Preſent Diſcontents:" and in 1775 ſhe publiſhed "An Addreſs to the People of England, Scotland, and Ireland, on the preſent important Criſis of Affairs." She wrote alſo "A Treatiſe on the Immutability of Moral Truth:" which ſhe afterwards re-publiſhed, with much other original matter, under the title of "Letters on Education." This work was publiſhed in 1790, at a period when men's minds were ready to admit bold theories on almoſt any ſubject, and it obtained much attention from the public. The author ſhewed herſelf an animated writer, and a ſhrewd and acute reaſoner. It will unqueſtionably repay any one, intereſted in the ſubject, the labour of a careful peruſal.

MACAW, MACCAW, or *Macao*, in *Ornithology*, the name of a large ſpecies of parrot, diſtinguiſhed alſo by the length of its tail. See PSITTACUS.

MACAW *Tree*, in *Botany*. See COCOS.

MACAY, in *Geography*, a town of Africa, in the kingdom of Damel. N. lat. 15° 10′. W. long. 15° 55′.

MACBETH. This admirable tragedy of our matchleſs dramatiſt, Shakſpeare, from the ſongs of the witches, as ſet by Matthew Lock in the time of Charles II., was regarded as a kind of opera. See DRAMATIC *Muſic*.

MACBETH, in *Biography*, an uſurper and tyrant, whom the immortal Shakſpeare has conſigned to everlaſting infamy, flouriſhed in Scotland about the middle of the 11th century. At this period Duncan was king, a mild and humane prince, but not at all poſſeſſed of the genius and diſpoſition for governing a country ſo turbulent, and ſo infeſted by the intrigues and animoſities of the great. Macbeth, a powerful nobleman, and nearly allied to the crown, not contented with curbing the king's authority, carried ſtill farther his mad ambition: he murdered Duncan at Inverneſs, and then ſeized upon the throne. Fearing leſt his ill-gotten power ſhould be ſtripped from him, he chaſed Malcolm Kenmore, the ſon and heir, into England, and put to death Mac Gill and Banquo, the two moſt powerful men in his dominions. Macduff next becoming the object of his ſuſpicions, he eſcaped into England, but the inhuman uſurper wreaked his vengeance on his wife and children, whom he cauſed to be cruelly butchered. Siward, whoſe daughter was married to Duncan, embraced, by Edward's orders, the protection of this diſtreſſed family. He marched an army into Scotland, and having defeated and killed Macbeth in battle he reſtored Malcolm to the throne of his anceſtors. The tragedy founded upon the hiſtory of Macbeth, though contrary to the rules of the drama, contains an infinity of beauties with reſpect to language, character, paſſion, and incident, and is thought to be one of the beſt pieces, of the very beſt maſter in this kind of writing, that the world ever produced. "The danger of ambition," ſays Dr. Johnſon, "is well deſcribed; and the paſſions are directed to their true ends." And the author of the Philoſophic Arrangements ſays, "it is not only admirable as a poem, but one of the moſt moral pieces exiſting." Hume's Hiſt. Biog. Dramatica: Shakſpeare Illuſtrated.

MACBRIDE, DAVID, M.D. a diſtinguiſhed phyſician, was born at Ballymony, in the county of Antrim, on the 26th of April, 1726. He was deſcended from an ancient family of his name in the ſhire of Galloway, in Scotland; but his grandfather, who was bred to the church, was called to officiate at Belfaſt to a congregation of Preſbyterians, and his father became the miniſter of Ballymony, where David was born. Having received the firſt elements of his education at the public ſchool of this place, and ſerved his apprenticeſhip to a ſurgeon, he went into the navy, firſt in the capacity of mate to an hoſpital-ſhip, and ſubſequently in the rank of ſurgeon, in which ſtation he remained for ſome years preceding the peace of Aix-la-Chapelle. At this period he was led, from the frequent opportunities of witneſſing the attacks of ſcurvy, which a ſeafaring life afforded him, to inveſtigate the beſt method of cure for that diſeaſe, upon which he afterwards publiſhed a treatiſe. After the peace of Aix, Mr. Macbride went to Edinburgh and London, where he ſtudied anatomy under thoſe celebrated teachers Doctors Monro and Hunter, and midwifery under Smellie. About the end of 1749, he ſettled in Dublin as a ſurgeon and accoucheur; but his youth and remarkable baſhfulneſs occaſioned him to remain a number of years in obſcurity, little employed; although he was endeared to a ſmall circle of friends by his great abilities, amiable diſpoſitions, and his general knowledge in all the branches of polite literature and the arts. In 1764, he publiſhed his "Experimental Eſſays," which were every where received with great applauſe, and were ſoon tranſlated into different languages; and the ſingular merit of this performance induced the univerſity of Glaſgow to confer the degree of doctor of phyſic on its author. The improvement introduced by Dr. Macbride in the art of tanning, by ſubſtituting lime-water for common water in preparing ooze, procured him the honour of a ſilver medal from the Dublin Society, in the year 1768, and of a gold medal of conſiderable value from the Society of Arts and Commerce in London.

For ſeveral years after Dr. Macbride obtained his degree, he employed part of his time in the duties of a medical teacher, and delivered, at his own houſe, a courſe of lectures on the theory and practice of phyſic. Theſe lectures were publiſhed, in 1772, in one vol. 4to., under the title of "An Introduction to the Theory and Practice of Medicine," and a ſecond edition appeared in 1777. It was tranſlated into Latin, and publiſhed at Utrecht, in 2 vols. 8vo. in 1774. This work diſplayed great acuteneſs of obſervation, and very philoſophical views of pathology, and contained a new arrangement of diſeaſes, which was deemed of ſo much merit by Dr. Cullen, that an outline of it was given by that celebrated profeſſor, in his Compendium of Noſology. Of the five claſſes, however, into which Dr. Macbride diſtributed diſeaſes, the genera and ſpecies of the firſt only were detailed.

The talents of Dr. Macbride were now univerſally known, his character was duly appreciated, and his profeſſional emoluments increaſed rapidly; for the public, as if to make amends for former neglect, threw more occupation into his hands, than he could accompliſh either with eaſe or ſafety. Although much haraſſed both in body and mind, ſo as to have ſuffered, for ſome time, an almoſt total incapacity for ſleep, he continued in activity and good ſpirits until the end of December 1778, when an accidental cold brought on a fever and delirium, which terminated his life on the 13th of that month, in the 53d year of his age: his death was ſincerely lamented by perſons of all ranks. See Edin. Med. Commentaries, vol. vii. p. 105. Cullen, Synops. Noſol. Method. vol. i.

MACCABÆUS, Judas, a valiant leader of the Jews, was the third ſon of Mattathias, of the Aſmonæan family, whom he ſucceeded as general of his nation in the year 166 B.C. At this period the Jews were in a ſtate of revolt againſt Antiochus Epiphanes, and Judas, with a ſmall body of men, haraſſed the Syrians, Samaritans, and apoſtate Jews, and filled the country with the terror of his name. After ſome important ſucceſſes, and being left maſter of the field, Judas marched to Jeruſalem, where he purified the city and temple, the latter of which was again dedicated, and a commemoratory feſtival, on this occaſion, was inſtituted, which was ordered to be perpetual. The death of Antiochus gave the Jews ſome reſpite, but hoſtilities were ſoon renewed, and Judas diſplayed his uſual vigour and military proweſs. Lyſias, the commander of the Syrians, was now his chief antagoniſt; him he defeated and obliged to ſeek terms of peace. After this the Syrian general invaded Judea a ſecond time, and obliged Judas to take refuge in Jeruſalem. He beſieged the city, which would, probably, notwithſtanding the valour of its defender, have been obliged to ſurrender for want of proviſions, had not the hoſtile army been haſtily recalled by a rebellion in their own country. After Demetrius Soter had obtained the crown of Syria, the war with the Jews was renewed: Bacchides, marching with the flower of his army, ſurpriſed Judas at the head of a ſmall body of men, of whom, all but eight hundred, deſerted at the approach of the enemy. With theſe he made a deſperate reſiſtance, till he fell upon a heap of ſlaughtered enemies. This was in the year 161 B.C.: the news of his death cauſed the utmoſt grief and conſternation at Jeruſalem, where a general mourning was made for him, and he was celebrated in ſongs, as one of the greateſt heroes of the nation. His body was recovered, and interred in the ſepulchre of his father at Modin. Books of Maccabees. Joſephus.

MACCABEES, two apocryphal books of Scripture, containing the hiſtory of Judas and his brothers, and their wars againſt the Syrian kings in defence of their religion and liberties, ſo called from Judas, the ſon of Mattathias, (ſee Mattathias,) ſurnamed *Maccabæus*, as ſome ſay from the word מכבי, formed of the initials of באלים יהוה מי כמכה, q. d. *Who is like unto thee, O Lord, among the Gods* (Exod. xv. 11.); which was the motto of his ſtandard: whence thoſe who fought under his ſtandard were called Maccabees, and the name was generally applied to all who ſuffered in the cauſe of the true religion, under the Egyptian or Syrian kings. This name, formed by abbreviation according to the common practice of the Jews, diſtinguiſhed Judas Maccabæus by way of eminence, as he ſucceeded his father B.C. 166 in the command of thoſe forces, which he had with him at his death, and being joined by his brothers, and all others that were zealous for the law, he erected his ſtandard, on which he inſcribed the abovementioned motto. Thoſe alſo who ſuffered under Ptolemy Philopater of Alexandria, fifty years before this period, were afterwards called Maccabees; and ſo were Eleazar, and the mother and her ſeven ſons, though they ſuffered before Judas erected his ſtandard with the motto, from which the appellation originated. And therefore, as theſe books which contain the hiſtory of Judas and his brothers, and their wars againſt the Syrian kings, in defence of their religion and liberties, are called the *firſt* and *ſecond* books of the Maccabees; ſo that book which gives us the hiſtory of thoſe, who, in the like cauſe, under Ptolemy Philopater, were expoſed to his elephants at Alexandria, is called the *third* book of the Maccabees, and that which is written by Joſephus of the martyrdom of Eleazar, and the ſeven brothers and their mother, is called the *fourth* book of the Maccabees.

The *firſt* book of the Maccabees is an excellent hiſtory, and comes neareſt to the ſtyle and manner of the ſacred hiſtorians of any extant. It was written originally in the Chaldee language, of the Jeruſalem dialect, and was extant in this language in the time of Jerom, who had ſeen it. From the Chaldee it was tranſlated into Greek, from the Greek into Latin, and alſo into Engliſh. Theodotion is conjectured to have tranſlated it into Greek; but it was probably more ancient, as we may infer from its uſe by ancient authors, as Tertullian, Origen, and others. It is ſuppoſed to have been written by John Hyrcanus, the ſon of Simon, who was prince and high prieſt of the Jews near thirty years, and began his government at the time where this hiſtory ends. It contains the hiſtory of forty years, from the reign of Antiochus Epiphanes, to the death of Simon the high prieſt; that is, from the year of the world 3829, to the year 3869; 131 years before Chriſt. The *ſecond* book of the Maccabees begins with two epiſtles ſent from the Jews of Jeruſalem to the Jews of Egypt and Alexandria; to exhort them to obſerve the feaſt of the dedication of the new altar erected by Judas, on his purifying the temple. The firſt was written in the 169th year of the era of the Seleucidæ, *i. e.* before Chriſt 144; and the ſecond in the 188th year of the ſame era, or 125 before Chriſt; and both appear to be ſpurious. After theſe epiſtles follows the preface of the author to his hiſtory, which is an abridgment of a larger work, compoſed by one Jaſon, a Jew of Cyrene, who wrote in Greek the hiſtory of Judas Maccabæus, and his brethren, and the wars againſt Antiochus Epiphanes, and Eupator his ſon. The two laſt chapters contain events under the reign of Demetrius Soter, the ſucceſſor of Antiochus Eupator, and contain ſuch varieties in their ſtyle, as render it doubtful whether they had the ſame author as the reſt of the work. This ſecond book does not, by any means, equal the accuracy and excellency of the firſt. It contains an hiſtory of about fifteen years, from the execution of Heliodorus's commiſſion, who was ſent by Seleucus to fetch away the treaſures of the Temple, to the victory obtained by Judas Maccabæus over Nicanor; that is, from the year of the world 3828, to the year 3843, 157 years before Chriſt. Calmet.

There are in the Polyglot bibles, both of Paris and London, Syriac verſions of both theſe books; but they, as well as the Engliſh verſions which we have among the apocryphal writers in our bibles, are derived from the Greek. For a further account of Judas Maccabæus, and of his brothers, whoſe hiſtory is recorded in the firſt and ſecond books of the Maccabees, and alſo by Joſephus in his Antiquities; we refer to the article JEWS, and alſo to the biographical article JUDAS MACCABÆUS. The *third* book of the Maccabees contains the hiſtory of the perſecution of Ptolemy Philopater againſt the Jews in Egypt, and their ſufferings under it; and ſeems to have been written by ſome Alexandrian Jew in the Greek language, not long after the time of Siracides. This book, with regard to its ſubject, ought to be called the firſt, as the things which are related in it occurred before the Maccabees, whoſe hiſtory is recorded in the firſt and ſecond books; but as it is of leſs authority and repute than the other two, it is reckoned after them. It is extant in Syriac, though the tranſlator did not ſeem to have well underſtood the Greek language. It is in moſt of the ancient manuſcript copies of the Greek Septuagint, particularly in the Alexandrian and Vatican, but was never inſerted into the vulgar Latin verſion of the bible, nor conſequently into any of our Engliſh copies. The firſt authentic mention we have of this book is in Euſebius's Chronicon. It is alſo named with two other books of the Maccabees in the 85th of the apoſtolic canons. But it is uncertain when that canon was added. Grotius thinks that this book was written after the two firſt books, and ſhortly after the book of Eccleſiaſticus, from which circumſtance it was called the *third* book of Maccabees. Moreover, Joſephus's hiſtory of the martyrs that ſuffered under Antiochus Epiphanes, is found in ſome manuſcript Greek bibles, under the name of the *fourth* book of the Maccabees. This book, aſcribed to Joſephus, occurs under the title "Concerning the Empire or Government of Reaſon;" but learned men have expreſſed a doubt whether this was the book known to the ancients as the *fourth* book of the Maccabees. Philoſtratus, Euſebius, and St. Jerom, knew the book "Concerning the Government of Reaſon," and aſcribed it to Joſephus, by the name of the book of the Maccabees. St. Gregory Nazianzen, St. Ambroſe, and St. Chryſoſtom, in the characters they have given of the ſeven Maccabees, and of old Eleazar, have plainly followed what we find in this book. The author has enlarged and adorned the hiſtory of Eleazar, and of the ſeven brothers the Maccabees, who are ſaid to have ſuffered martyrdom with their mother, as it has been ſaid, chiefly on the authority of Rufinus, who has given the names of the ſeven brothers, and of their mother, at Antioch. (2 Mac. vi. vii.) Others, however, have ſuppoſed, that the ſcene of the martyrdom of the ſeven brethren was at Jeruſalem. As it was deſigned for an example of terror to the Jews of Judæa, it would have loſt its force, if it had been executed any where elſe beſides that country. Thoſe who maintain that they ſuffered at Antioch, allege, that their tombs were ſhewn there in the time of St. Jerom, and that a church, dedicated under their name, was found there in the time of St. Auſtin. The firſt of the ſeven brethren, as the ſtory is related, having declared to the king that he would die ſooner than violate the laws of God, was ſeized by the executioners, who cut out his tongue, and the extremities of his hands and feet, and tore off the ſkin of his hand. While ſtill alive, after being thus mangled, he was thrown into a burning pan, heated over a fierce fire. Such is the account in 2 Mac. vii. 2. 7. The "Government of Reaſon" declares, that the executioner, having ſtripped off his clothes, tied his hands behind his back, and whipped him with ſcourges, without his indicating the leaſt ſign of pain. Afterwards they fixed him upon a wheel, where, after having had his limbs ſhattered to pieces, he expoſtulated with Antiochus, reproached him for his barbarity, and inſulted him on account of all his unſucceſsful attempts. Then the executioner, raiſing the wheel upon which he was extended, and lighting a fire under it, thus conſumed him by a new torture. He died, exhorting his brethren to manifeſt a ſimilar conſtancy. The other brothers alſo ſuffered by the moſt cruel tortures which the king could inflict; but it is needleſs to recount them. The mother of theſe martyrs alſo ſuffered death, as ſome ſay, by throwing herſelf into the fire, to evade the cruelty practiſed on her ſons, and threatened to herſelf. The church of Rome has celebrated a feaſt, Auguſt 1, in honour of theſe martyrs; who were the firſt, and for a long time the only martyrs of the Old Teſtament, in honour of whom altars and temples were erected; and they are the only ſaints of that kind, for whom there remains an office or breviary commemorative in the Roman Breviary. The ſufferings of theſe ſeven brethren, and likewiſe of Eleazar, related 2 Mac. c. vi. are entirely omitted in the firſt book of Maccabees; although the author of it there writes of the Jewiſh affairs, and of the ſufferings of the Jews in the time of Antiochus. We add that there is not any notice taken of this Eleazar, or theſe ſeven brethren, or their mother, by Joſephus, in any of his authentic writings; though he had twice a fair occaſion of mentioning them, once in his "Hiſtory of the Jewiſh War," l. i. and again in his "Antiquities," l. xii. cap. 5. It is preſumed that he would have mentioned a fact ſo remarkable, if it had really occurred. As to the work above-mentioned, "Of the Empire of Reaſon," which has been aſcribed to him, many learned men, as Cave ſays, deny it to be his; and Mr. Whiſton, in his Engliſh tranſlation of all the genuine writings of Joſephus, has omitted this. Dr. Lardner thinks that it was the work of ſome Chriſtian. This hiſtory wants certain internal characters of credibility. The fact itſelf is very extraordinary, inſomuch that it is very improbable, and almoſt incredible. The whole ſtory has the appearance of a contrived fiction. The ſufferers are not deſcribed ſo particularly as they ought to be, and the relations generally are incredible. Beſides, it is improbable that theſe ſeven brothers ſhould have been examined, tortured, and ſlain, one after another, in the preſence of king Antiochus; for ſuch examinations and executions are generally delegated to officers: nor is it ſaid, or even hinted, where theſe perſons ſuffered. It has been ſaid, however, that the writer of the epiſtle to the Hebrews refers to this hiſtory, and thus aſſures us of its truth. (Heb. xi. 35.) But it is very far from being clear or certain, that there is a reference to this hiſtory in that text. Hallet, Lardner, and others, deny it. See Lardner's Works, vol. xi. p. 269, &c.

MACCHERINI, La Signora, in *Biography*, a female Italian ſinger, engaged as firſt woman at the Opera-houſe in 1780, on a falſe report of her great abilities by her countrymen in London, diſappointed every hearer.

MACCHIAVELLI, Nicholas, a celebrated political writer and hiſtorian, was born of a good family, at Florence, in 1469. He firſt diſtinguiſhed himſelf as a dramatic writer, and produced plays that were acted with great applauſe at Rome. Soon after he had entered public life, he was ſuppoſed to have participated in a conſpiracy againſt the houſe and family of Medici; but being "put to the queſtion" on the ſubject, he had the fortitude to endure the torture without uttering the ſlighteſt confeſſion, and was ſet at liberty. He was afterwards raiſed to high honours in the ſtate, and became ſecretary to the republic of Florence, the duties of which high office he performed with great fidelity. He was likewiſe employed in embaſſies to king Lewis XII. of France; to the emperor Maximilian; to the college of cardinals; to the pope, Julius II., and to other Italian princes. Notwithſtanding the revenues which muſt have accrued to him in theſe important ſituations, he left a large family at his death in a ſtate of indigence, a circumſtance that proves he had acted with integrity, and that the love of money had no influence on his mind. He died in 1530. Beſides his plays, his chief works are, 1. "The Golden Aſs," in imitation of Lucian and Apuleius; 2. "Diſcourſes on the firſt Decade of Livy;" 3. "A Hiſtory of Florence;" 4. "The Life of Caſtruccio Caſtracani;" 5. "A Treatiſe on the Military Art;" 6. "A Treatiſe on the Emigration of the Northern Nations;" 7. A Treatiſe, entitled "Del Principe," *the Prince*. This famous treatiſe was firſt publiſhed in 1515, and was intended as a ſequel to his diſcourſes on the firſt decade of Livy, which diſcourſes are replete with juſt and profound reflections on the principles of popular government, and exhibit him as a warm friend of liberty; but "The Prince" has been generally regarded as the manual of a tyrant; all its maxims and counſels being directed to the maintenance of power, however acquired, and by any means. It was dedicated to a nephew of pope Leo X., was printed at Rome, republiſhed in other Italian cities, and was long read with attention, and even applauſe, without cenſure or reply. The practice of politicians at that time was ſo much in uniſon with its maxims, that neither ſurpriſe nor deteſtation ſeems to have been excited by an open expoſure of the uſual arts of government. The writer's intention in this work has been a matter of much controverſy; ſome have held him up as an abandoned promoter of tyranny, and others have maintained that he was its concealed but decided enemy, who meant to put "the people" on their guard againſt its machinations. A modern critic, however, thinks it probable, from the character of the man, that he wrote it without any moral purpoſe whatever; and merely, like a mathematician demonſtrating a problem, inveſtigated the principles by which uſurped power might be maintained, leaving the application to princes or ſubjects, as chance ſhould direct. It has, nevertheleſs, affixed to his name a laſting ſtigma, and Machiaveliſm is become a received appellation for perfidious and infamous politics. When once the ſyſtem was expoſed, a multitude of opponents to it ſtarted up, in almoſt every enlightened country on the globe; among whom, and one of the lateſt, was Frederic the Great, king of Pruſſia, before he commenced thoſe plans of aggrandizement, that he purſued very much in the ſpirit of the work which he had ably anſwered. Of the hiſtorical writings of Machiavel, the "Life of Caſtrucio Caſtracani" is conſidered as partaking too much of the character of a romance; but his "Hiſtory of Florence," compriſing the events of that republic, between the years 1205 and 1494, is a very valuable performance, and one of the earlieſt of the good Italian hiſtories. It was written while the author ſuſtained the office of hiſtoriographer of the republic. He has been charged with miſrepreſentation; but his character, as an hiſtorian, has been ably vindicated, and his ſtyle and compoſition, as a proſe writer, are held in high eſtimation. His verſes do not rank among the firſt, or even the ſecond rate productions of Italian poetry; and his comedies, however they might appear in public repreſentation, are not formed on the pureſt models. The works of this writer were collected in two volumes 4to. in 1550, and they have been republiſhed in Amſterdam, London, and Paris. Gen. Biog. See Machiavelism.

MACCLESFIELD, called in ancient records *Maxfield*, in *Geography*, a populous, corporate, and borough-town of Cheſhire, England, is built on the ſide of a ſteep hill, at the diſtance of 18 miles from Mancheſter, and 166 from London. It is part of the pariſh of Preſtbrug, in the hundred of Macclesfield. Radal, earl of Cheſter, firſt conſtituted it a borough; and in or near the year 1261, the prince of Wales, afterwards king Edward I., made it a free borough, and granted the burgeſſes a mercatorial guild, and other privileges. By the conditions of the charter thus obtained, the burgeſſes were required to grind only at the earl's mill, and to bake at his oven. This oven, or bakehouſe, is ſtill veſted in the crown, and a leaſe of it was granted, in 1791, for twenty-four years and a half. By a charter of queen Elizabeth's, the corporate body was to conſiſt of 24 capital burgeſſes; but a later charter, from king Charles II., names a town-clerk, a coroner, two ſerjeants at mace, &c. as part of the corporation. Among other articles delivered into the cuſtody of the ſerjeants at mace, in the year 1620, was "a bridle for a curſt queane." The market, which is held on Mondays, was formerly very conſiderable for corn, but has declined. The annual fairs are five, principally for cloth, cutlery, toys, and pedlars' ware. The ſilk and cotton trade is carried on in this town to a conſiderable extent, there being nearly thirty ſilk mills, ſome of them on a large ſcale, and about ten cotton factories: a great quantity of goods of both ſorts is alſo manufactured in private houſes; there are ſeveral muſlin, ſilk-weaving, and twiſt factories. The weaving of ſilk handkerchiefs, and the making of ferret and calico, are increaſing manufactures: here are five or ſix dye-houſes, principally for ſilk, a tape manufactory, and a bleaching ground. According to the returns made to parliament under the population act of 1800, the number of houſes was then 1527, the number of inhabitants was ſtated to be 8743, of whom 8509 were ſaid to be employed chiefly in trade, manufactures, or in handicraft. The population has ſince that period been conſiderably increaſed. In the year 1791, an act was paſſed for incloſing the commons and waſte grounds within the borough and manor of Macclesfield. By this act, all encroachments within the manor (except ſuch as had occurred within ſixty years, and had no buildings), were ſecured on certain terms to their reſpective poſſeſſors; the manorial rights of the crown, with reſpect to the ſoil, mines, and minerals of the ſeveral waſte-grounds within the manor and borough were extinguiſhed, with the reſerve of coal-mines: as a compenſation for which conceſſions, an allotment of 118½ acres was made to his majeſty, which allotment, and the right of digging coal, were ſold in 1803, under the land-tax redemption act to Charles Cooke of this town. The corporation are entitled to all ſprings and water-courſes for ſupplying the town with water, from which ſources, with the tolls of the market and fairs, a conſiderable emolument is derived. A court of record is held once a month for the liberty of the hundred, and another for the manor and foreſt; a court leet is alſo held for theſe juriſdictions. In former times the juſtices of Cheſter ſat as juſtices in eyre at Macclesfield, and priſoners for felony and other crimes were tried there, and ſuffered the ſentence of the law. After this practice was diſcontinued, courts were held by the king's ſteward or his deputy. Two ſeſſions are now held in May and November, beſides the monthly courts before-mentioned.

In a ſtreet, called Backwall-Gate, are ſome remains of a manſion of the dukes of Buckingham. Smith, in his deſcription of Cheſhire (1585), deſcribes it as "a huge place, all of ſtone, in manner of a caſtle, which belonged to the duke of Buckingham, but now gone to decay." Webb, writing in 1622, ſays, "in this towne are yet ſeen ſome ruines of the ancient manor-houſe of the renowned duke of Buckingham, who (as yet report goeth) kept there his princely reſidence, about the time of king Edward IV., of whoſe great hoſpitality there, much by tradition is reported."

Other ancient manſions of this town were formerly occupied by families of diſtinction: among theſe was Stapleton-hall, belonging to the Stapletons of Upton; Beate-hall, inhabited by the earl of Courtown, is now a public-houſe; Worth-hall was the town reſidence of the family of Worths: and is traditionally ſaid to have been the birth-place of archbiſhop Savage.

The parochial chapel of this town was originally built by king Edward I. in the year 1278; it was almoſt rebuilt, and greatly enlarged, in 1740. On the ſouth ſide of this chapel is an oratory, or burial chapel, which belongs to the Savage family; ſeveral of whom were interred here. It now belongs to the earl of Cholmondeley. In the Legh chapel are ſome ſepulchral memorials of the family of Legh of Lyme.

A new chapel was erected at Macclesfield in the year 1775, by Charles Roe, eſq. and an act of parliament was obtained in 1779, when it was called Chriſt's-church, or chapel, and the living was made a perpetual cure, or benefice, to be ſubject to the biſhop of Cheſter. In the chancel is a handſome marble monument by Bacon, for the founder, who died in 1781.

In this town are two meeting-houſes for Methodiſts, and one for each of the following ſects: Preſbyterians, Quakers, and Independents. A grammar-ſchool was founded here by ſir John Percival, knt., and not by king Edward VI., as commonly ſtated. This monarch increaſed its revenues, by giving lands and houſes in and near the city of Cheſter. An act of parliament was obtained, in 1768, to regulate the management, and define the conſtitution of this noted ſeminary. Four miles S.S.E. of the town is the townſhip of Macclesfield foreſt. Lyſons's Magna Britannia, vol. ii. part 2. 4to. 1810.

MACDONALD, Andrew, in *Biography*, was born at Leith, where he was educated, chiefly by the aſſiſtance of biſhop Forbes. For ſome time he had the charge of a chapel at Glaſgow, in which city he publiſhed a novel, entitled "The Independent." He afterwards came to London, and wrote for the newſpapers. His works were lively, ſatirical, and humorous, and were publiſhed under the ſignature of Matthew Bramble. He naturally poſſeſſed a fine genius, and had improved his underſtanding with claſſical and ſcientific knowledge; but for want of connections in this ſouthern part of the united kingdom, and a proper opportunity to bring his talents into notice, he was always embarraſſed, and had occaſionally to ſtruggle with great and accumulated diſtreſs. He died in the 33d year of his age, at Kentiſh Town, in Aug. 1790, leaving a wife and infant daughter in a ſtate of extreme indigence. A volume of his "Miſcellaneous Works" was publiſhed in 1791, in which were compriſed; "The fair Apoſtate," a tragedy; "Love and Loyalty," an opera; "Princeſs of Tarento," a comedy; and "Vimonda," a tragedy. Biog. Dramatica.

MACDOWAL's Bay, in *Geography*, a bay on the W. coaſt of the iſland of Java.

MACDUFF, a conſiderable ſea-port town ſituated on the banks of the Moray frith, in the pariſh of Gamvie, and ſhire of Banff, Scotland, at the diſtance of two miles from the county-town. Previous to the year 1732, it was merely a trifling village, compoſed of a few fiſhermen's huts, with no other harbour for their boats but a ſandy creek. It is now, through the exertions of the earl of Fife, on whoſe property it ſtands, a very thriving place. The houſes, which are eſtimated at about 300 in number, are generally built with much neatneſs, and arranged into regular ſtreets of a commodious width. The population exceeds twelve hundred perſons, a great proportion of whom is engaged in the extenſive fiſheries which have been eſtabliſhed on this part of the coaſt. There are ſeveral ſhips belonging to this town employed in the Baltic and London trade. Many veſſels from other ports likewiſe reſort hither; the harbour, formed at the expence of the nobleman already mentioned, being conſidered one of the ſafeſt and moſt commodious in the Moray frith. As this place lies at ſome diſtance from the pariſh church, the ſame noble individual has alſo erected a chapel of eaſe here, and pays a ſuitable ſalary to the clergyman ſettled in it. A great variety of little fiſhing villages lie along the ſhore on both ſides, and on the oppoſite bank of the river Doveran.

MACE, in *Ancient Armoury*, a weapon formerly much uſed by the cavalry of all nations, and likewiſe by eccleſiaſtics, who, in conſequence of their tenures, frequently took the field, but were, by a canon, forbidden to wield the ſword. The mace is commonly of iron; its figure much reſembles a chocolate-mill. Many ſpecimens may be ſeen in the Tower of London, and other armouries. It was not out of uſe long after the invention of hand-guns; for we read of its having been uſed by moſt nations more than 100 years ago; and in a medley, it is ſaid, they may be more ſerviceable than ſwords; for when they are guided by a ſtrong arm, we find that the party ſtruck with them was either felled from his horſe, or, having his head-piece beat cloſe to his head, was made to reel on his ſaddle, with the blood running plentifully from his noſe. This kind of mace, which is the ſame as that uſed by the Turks, is improperly called by ſome military writers the club of Hercules; the club given to that demi-god by the Grecian ſtatuaries, being a huge knotty limb of a tree. Father Daniel has engraved two weapons, ſhewn in the abbey of Roncevaux, as the maces of thoſe famous heroes of romance, Roland and Oliver, who are ſaid to have lived in the time of Charlemagne. One is a large ball of iron, faſtened with three chains to a ſtrong truncheon, or ſtaff, about two feet long; the other is of mixed metal, in the form of a channelled melon, faſtened alſo to a ſtaff by a triple chain: theſe balls weigh eight pounds. At the end of both the ſtaves are rings for holding ends or leathers to faſten them to the hand. Contrivances like theſe, except that the balls were armed with ſpikes, were long carried by the pioneers of the trained bands, or city militia: they are generally called “Morning Stars.” The morning ſtar, or Morgan ſtern, was a weapon formerly uſed for the defence of trenches. It was a large ſtaff, banded about with iron, like the ſhaft of a halbert, having an iron ball at the end, with croſs iron ſpikes.

At preſent the mace is generally made of the precious metals, and highly ornamented and uſed as an emblem of the authority of the officers of ſtate before whom it is carried.

Mace, Thomas, in *Biography*, one of the clerks of Trinity college, Cambridge, in the ſeventeenth century, of quaint and ſingular memory, publiſhed in folio, 1676, a treatiſe, entitled “Muſick's Monument; or, a Remembrance of the beſt practical Muſick, both Divine and Civil, that has ever been known in the World;” a work that muſt not be forgotten among the curioſities of this period. It is impoſſible to deſcribe the ſtyle of this original book by any choice or arrangement of words, but the author's own. The work is divided into three parts; the firſt treats of pſalm-ſinging and cathedral muſic; the ſecond, of the noble lute, “now made eaſy, and all its occult, locked-up-ſecrets, plainly laid open; ſhewing a *general way* of procuring *invention* and playing voluntarily upon the lute, viol, or any other inſtrument, with two pretty devices, &c. In the third part the *generous viol*, in *its righteſt uſe*, is treated upon; with ſome *curious obſervations*, never before handled, concerning it, and muſic in general.”

In pſalm-ſinging the author recommends *ſhort-ſquare-even and uniform ayres*, and is “bold to ſay that many of our old pſalm-tunes are ſo *excellently good*, that art cannot *mend them* or make them better.” In ſpeaking of the difficulty of ſinging in tune, even with a good voice, he obſerves, that “with an *unſkilful-inharmonious-coarſe-grained-harſh-voice*, it is impoſſible. 'Tis *ſad* to hear what *whining*, *toling*, *yelling*, or *ſcreeking* there is in our *country congregations*, where, if there be no organ to compel them to harmonical unity, the people ſeem *affrighted* or diſtracted.”

The liberal uſe of compounds by the ingenious maſter Mace gives his language a very Grecian appearance. He doubts not but that there are “many *rational-ingenious-well-compoſed-willing-good-Chriſtians*, who would gladly *ſerve God* aright, if poſſibly they knew but how;” and therefore he adviſes the purchaſe of an organ of thirty, forty, fifty, or ſixty pounds; and then, “the clerk to learn to *pulſe* or *ſtrike* the pſalm-tunes, which he offers himſelf to teach for thirty or forty ſhillings; and the clerk afterwards may inſtruct all the boys in the pariſh for a ſhilling or two a-piece to perform the buſineſs as well as himſelf. And thus by *little* and *little*, the pariſh will *ſwarm* or abound with organiſts.”

The lute and viol are maſter Mace's favourite inſtruments, concerning the effects of which, and, indeed, of muſic in general, he is a great rapturiſt. On the lute, though “he had occaſion to *break both his arms*, by reaſon of which he could not make the *nerve-ſhake well*, nor ſtrong; yet, by a certain *motion of his arm*, he had gained ſuch a *contentive-ſhake*, that his ſcholars aſked him frequently how they ſhould do to get the like?”

We ſhall not attempt to recreate our readers with more extracts from this matchleſs, though not ſcarce, book; but recommend its peruſal to all who have taſte for exceſſive ſimplicity and quaintneſs, and can extract pleaſure from the ſincere and undiſſembled happineſs of an author, who, with exalted notions of his ſubject and abilities, diſcloſes to his reader every inward working of ſelf-approbation in as undiſguiſed a manner, as if he were communing with himſelf in all the plenitude of mental comfort and privacy. We ſhall, however, preſent ſuch readers with an advertiſement from good maſter Mace, that was written on his arrival in London, 1690, fourteen years after the publication of his book. We found it in the Britiſh Muſeum, N° 5936, in a collection of title-pages, devices, and advertiſements.

An Advertiſement.

“To all Lovers of the beſt *Sort* of *Muſick*.”

“Men ſay the times are ſtrange——'tis true:
'Cauſe many ſtrange things hap to be.
Let it not then ſeem ſtrange to you
That here one ſtrange thing more you ſee.”

“That is, in Devereux-court, next the Grecian coffee-houſe, at the Temple back-gate, there is a deaf perſon teacheth muſic to perfection; who, by reaſon of his great age, v. 77, is come to town, with his whole ſtock of rich *muſical furniture*, v. inſtruments and books to put off, to whomſoever delights in ſuch choice things; for he has nothing light or vain, but all *ſubſtantial* and ſolid MUSIC. Some particulars do here follow:

“1. There is a late invented ORGAN; which (for private uſe) excels all other faſhioned organs whatever; and for which, ſubſtantial-artificial *reaſons* will be given; and (for its beauty) it may become a nobleman's dining-room.

“2. There belongs to it a pair of fair, large-ſized *conſort-viols*, chiefly fitted and ſuited for That, or conſort uſe; *and 'tis great pity they ſhould be parted.*

“3. There is a *pedal harpſicon* (the abſolute beſt ſort of *conſort harpſicons* that has been invented); there being in it more than twenty *varieties*, moſt of them to come in with the foot of the player, without the leaſt hindrance of play (exceedingly pleaſant). And

“4. Is a ſingle *harpſicon*.

“5. A new invented inſtrument, called a *dyphone*, v. a *double lute*; it is both *theorbo* and *French-lute* complete; and as eaſy to play upon as any other lute.

“6. Several other *theorbos*, *lutes*, and *viols*, very good.

“7. Great ſtore of choice collections of the works of the *moſt famous compoſers*, that have lived in theſe laſt hundred years, as Latin, Engliſh, Italian, and ſome French.

“8. There is the *publiſher's* own *Muſick's Monument*; ſome few copies thereof he has ſtill by him to put off; it being a ſubſcribed book, and not expoſed to common ſale. All theſe will be ſold at very eaſy rates, for the reaſons aforeſaid; and becauſe (indeed) he cannot ſtay in town longer than four months (exactly).”

He farther adds, “if any be deſirous to partake of his experimental ſkill in this *high-noble-art*, during his ſtay in town, he is ready to aſſiſt them; and (haply) they may obtain that from him, which they may not meet withal elſewhere. He teacheth theſe five things, v. the *theorbo*, the *French-lute*, and the *viol*, in all their excellent ways and uſes; as alſo *compoſition*, together with the *knack* of procuring *invention* to young compoſers (the general and greateſt difficulty they meet withal), this laſt thing not being attempted

tempted by any author (as he knows of), yet may be done; though ſome has been ſo wiſe (or otherwiſe) to contradict it:

"Sed experientia docuit."

"Any of theſe five things may be learned ſo underſtandingly, in this little time he ſtays (by ſuch general rules as he gives, together with *Muſick's Monument*, written principally to *ſuch purpoſes*), as that any aptly inclined, may (for the future) teach themſelves without any other help."

Mace, Francis, a learned French prieſt, was born at Paris about the year 1640, and being deſigned for the church, he purſued his ſtudies with that view at the univerſity of his native city, where he took his degrees. His firſt public employment was that of ſecretary to the council for managing the domains and finances of the queen, conſort to Lewis XIV. It was not till the year 1685 that he took holy orders, when he was immediately appointed canon, veſtry-keeper, and rector of the royal collegiate and parochial church of St. Opportune, at Paris. He was a very diligent ſtudent as well in profane as in ſacred literature, and was celebrated for his popular talents as a preacher. He died in 1721, leaving behind him a great number of works that do honour to his memory, of which we ſhall mention "A Chronological, Hiſtorical, and Moral Abridgment of the Old and New Teſtament," in 2 vols. 4to.; "Scriptural Knowledge, reduced into Four Tables;" a French verſion of the apocryphal "Teſtaments of the Twelve Patriarchs;" of which Groſſeteſte, biſhop of Lincoln, gave the firſt Latin tranſlation, Grabe the firſt Greek edition, from MSS. in the Engliſh univerſities, and Whiſton an Engliſh verſion; "The Hiſtory of the Four Ciceros," which abound in learned and curious enquiries, and intended to prove, from the teſtimony of Greek and Latin hiſtorians, that the ſons of Cicero were as illuſtrious as their father. Moreri.

Mace, in *Commerce*, a ſmall gold coin, current in Sumatra, and ſome other Eaſt India iſlands. It weighs nine grains, and is worth about 14*d.* ſterling. Sixteen mace are equal 64 copangs = 4 pardows = a tale: and 2500 ſmall pieces of tin or lead, called caſhes, uſually paſs for a mace.

Mace, *Macis*, is a pretty thick, tough, unctuous membrane, reticular or variouſly chapt, of a lively reddiſh-yellow colour, approaching to that of ſaffron, enveloping the ſhell of the fruit, whoſe kernel is the nutmeg. The mace, when freſh, is of a blood-red colour, and acquires its yellow hue in drying. It is dried in the ſun, upon hurdles fixed above one another, and then, as it is ſaid, ſprinkled with ſea-water, to prevent its crumbling in carriage.

Mace has a pleaſant aromatic ſmell, and a warm, bitteriſh, moderately pungent taſte; it is a thin and flat membranaceous ſubſtance, of an oleaginous nature, and of a yellowiſh colour. We meet with it in flakes of an inch or more in length, which are divided into a multitude of irregular ramifications; it is of an extremely ſmooth ſurface, and of a tolerably cloſe texture, yet friable, and very eaſily cut to pieces. It is of an extremely fragrant, aromatic, and agreeable ſmell, and of a pleaſant, but acrid and oleaginous taſte; it is to be choſen new, not dry, and of a fragrant ſmell, tough, oleaginous, and of a good yellow. The people who collect the nutmeg fruit cut it open, and throw away the pulpy ſubſtance, or external coat; they then ſee the mace covering the nutmeg, wrapping itſelf every where round its outer woody ſhell. The mace is at this time of a red colour; they take it carefully off from the nutmeg, and lay it in the ſun for the whole day. In this time its colour, from a ſtrong blood-red, becomes duſky; it is after this carried to another place, where the ſun has leſs power, and there expoſed again to its rays, the few hours they reach thither. By this means it dries gently, and remains tough, and retains its fragrancy and colour in a great degree: if it were dried more haſtily, it would be whitiſh, brittle, and would loſe much of its ſmell; after this it is ſlightly ſprinkled over with ſea-water, and then put up into bales in which it is preſſed down firm and cloſe, by way of preſerving its fragrance and conſiſtence.

It is of an aſtringent and drying nature, and is uſed as a corrector in cardiac and cathartic compoſitions. In its general quality it is nearly ſimilar to the *nutmeg*, which ſee; the principal difference conſiſts in the mace being much warmer, more bitteriſh, leſs unctuous, and ſitting eaſier on weak ſtomachs; in its yielding by expreſſion a more fluid oil, and in diſtillation with water a more ſubtile volatile one. Lewis's Mat. Med.

Mace, *Oil of*, is a kind of ſebaceous matter, ſaid to be expreſſed from the nutmeg, and appearing to be a mixture of the groſs ſebaceous matter of the nutmeg, with a little of the eſſential or aromatic oil; both which may be perfectly ſeparated from one another by maceration or digeſtion in rectified ſpirit, or by diſtillation with water. The beſt ſort of this oil is brought from the Eaſt Indies in ſtone jars, and is ſomewhat ſoft, of a yellow colour, and of a ſtrong agreeable ſmell, much reſembling that of the nutmeg itſelf. There is another ſort brought from Holland in ſolid maſſes, generally flat, and of a ſquare figure of a paler colour, and much weaker ſmell. Lewis.

Mace, *Reed*, in *Botany*. See Typha.

MACEDA, in *Geography*, a town of Spain, in the province of Galicia; five miles S.E. of Santiago.

MACEDO, Fr. Francisco de Santo Agostinho, in *Biography*, a learned Portugueſe, was born at Coimbra in 1596, and at a very early age diſcovered premature and extraordinary proofs of memory and imitation. At the age of eleven he could repeat the whole of the Æneid, and compoſe good Latin verſes. He joined the company of the Jeſuits, which he quitted, and entered the Franciſcan order in the reformed province of St. Antonio. When the Braganzan revolution broke out, Macedo eſpouſed the patriotic ſide, was called to political exertions, and viſited Rome, Paris, and London with ambaſſadors of Joam IV. As he advanced in years he retired to Rome, where he obtained the profeſſorſhip of eccleſiaſtical hiſtory, and other offices in the college De Propaganda Fide; for ſome time he performed all the high duties attached to his ſeveral ſtations with credit, and to the entire ſatisfaction of the pope, whoſe favour he forfeited for refuſing to expunge a word in an epitaph written upon a ſervant of his holineſs. At Rome, and alſo at Venice, he engaged in many learned diſputes with characters of the firſt literary reputation. To all his opponents Macedo replied moſt readily and without the ſmalleſt embarraſſment, correcting their falſe quotations, and confuting their arguments; and he is ſaid to have crowned the whole by reciting a thouſand extempore verſes, and an epigram in praiſe of the city of Venice, which epigram was by order of the republic written under his picture, and placed in the library of St. Mark. From the wonderful powers of his memory he obtained the title of the walking Cyclopædia. He died in 1681, at the great age of eighty-five. He left a vaſt multitude of works either in manuſcript or in print; he eſtimated the number of verſes which he had made at a million and a half. Of this prodigious number, ſays Mr. Southey, nobody now reads a ſingle line. Gen. Biog.

MACEDONIA, in *Ancient Geography*, a country of Europe, diſtinguiſhed by various appellations, belonging to one or other of its diſtricts, according as the people who inhabited thoſe diſtricts happened to prevail. In the moſt ancient times it took its name from Æmathia, a denomination derived from Æmathius, a prince of great antiquity; but afterwards the Greeks called it Macedonia, either from king Macedo, a deſcendant, as ſome pretend, from Deucalion, or, as others ſay, by an eaſy change of Mygdonia, the name of one of its provinces, into Macedonia. Its boundaries have been very various, ſometimes more extended and ſometimes more confined, according to the good or bad fortune of its reigning princes. It was bounded originally on the E. by the Ægean ſea, on the S. by Theſſaly and Epirus, on the W. by the Adriatic, or the Ionian ſea, and on the N. by the river Strymon and the Scardian mountains, afterwards by the river Neſſus, or Neſtus. Pliny ſays, that no leſs than 150 different nations were ſeated within its territory, and Mela tells us, that it had as many nations as cities; but in the time of Ptolemy, it appears from his geography, that this number was very conſiderable. Livy (c. xxx.) comprehends the ſeveral diviſions of Macedonia under four principal parts, which he deſcribes as follows: "Pars prima, Biſaltas habet fortiſſimos viros: trans Neſſum amnem incolunt et circa Strymonem, &c." This part was fertile, contained mines, and had for its principal town Amphipolis, which guarded the entrance into Macedonia, towards the eaſt. "Secunda pars, celeberrimas urbes Theſſalonicam et Caſſandriam habet." To this part was joined Pallena, a country very fertile, and abundant in grain, and having good ports. "Tertia regio, nobiles urbes Edeſſam et Beræam, et Pellam et Vettiorum bellicoſam gentem: incolas quoque permultos Gallos et Illyrios impigros cultores." "Quartam regionem Eordæi, et Lynceſtæ, et Pelagones incolunt. Juncta his Atintania et Stymphalis et Elimiotis." Cellarius diſtinguiſhes "Macedonia propria," from Macedonia adjuncta." Macedonia propria, or Macedon proper, contains the following parts. 1. In this part were the *Alompii* in the north, where the mountains Hæmus and the Scardus join. This country is called Almopia by Thucydides; and Livy places here mount Boreas. *Pelagonia*, called by Strabo τριπολις, becauſe it contained three towns, though Ptolemy aſſigns to it only two, is the fourth region of Livy, ſuppoſed to be the ſame with *Pæonia*. *Lyceſtis* or *Lynceſtis*, inhabited by the Lynceſtæ, lay to the S.W. of Pæonia. The chief town was Heraclea. *Eordæa*, inhabited by the Eordæi, was ſituated W. of the Lynceſtæ, or between the country of the Taulantii and Oreſtes. North of theſe was the territory of the Daſſaretæ, whoſe chief towns were Lychnides and Evia. The former was called Lychnidia by Polybius, and was pleaſantly ſituated near a lake of the ſame name. It is now called Ochrida. To this part belonged alſo a portion of *Elymiotis*; the reſt was in Illyria, as well as Candavia. 2. The ſecond part was compriſed between the rivers Erigon and Axius. Here are found the famous towns of Edeſſa, Berœa, and Pella. Livy places in this part the famous nation of Vettii. Towards the north lies a portion of Pæonia, called *Deuriopus*, which, according to Strabo, had three towns, *viz.* Bryanium, Alalcomenæ, and Stybæra. In the part of Pæonia, which was on this ſide of the Axius, was Armiſſa, which, according to Thucydides, was the firſt town of the kingdom of Perdiccas. *Æmathia* was the moſt conſiderable part of Macedonia, ſo as formerly to have given it its name; in which country we find Tyriſſa, Scydra, Meyza; and ſince among the *Cyrrheſtæ*, Cyrrhus, Idomené, Gortynia or Gordynia, Æge, and Pella. Towards the ſea was the ſmall country, called *Bottiæa*, or *Bottiætis*. As Herodotus attributes to this ſmall country the towns of Ichnæ and Pella, Cluvier conjectures that Æmathia was enlarged by its encroachments on this province. *Pieria* lay to the ſouth of this ſmall country, and in proceſs of time comprehended Bottiæa. In Pieria were the towns of Alorus, Methone, Pidna, called Citron, Dium, and others leſs conſiderable. The river Enipeus, flowing from the vallies of mount Olympus, diſcharged itſelf into the ſea, ſouth of Dium, and at its mouth was Phyla, a ſtrong town, built by Demetrius Gonatas. 3. The third part of Macedonia, according to Cellarius, was comprehended between the rivers Axius and Strymon; and this is the ſecond according to the diſtribution of Livy. In this part are found *Amphaxitis*, E. of the mouth of the Axius, on the Thermaic gulf. The moſt conſiderable town was Therma, which afterwards took the name of Theſſalonica, and is now called Salonichi. *Mygdonia* lay to the N. of the Thermaic gulf, but did not extend to the ſea. Here were the towns of Antigonea and Stobi, Phyſca, Terpillas, Aſſorus, and Xylopolis; and by extending this part towards the ſouth, it will be made to comprehend the towns of Apollonia and Arethuſa. Thucydides places immediately after Mygdonia, *Greſtonia*, *Anthemus*, and *Biſaltia*. *Anthemus* probably derived its name from the town of Anthemus, placed by M. d'Anville towards the E. of Amphaxitis, near the ſource of the Rechius. *Greſtonia* or *Creſtonia*, was ſituated N.E. of Amphaxitis, and had a town of the ſame name. The Echedorus had its ſource in this country, and ran from hence into Mygdonia. *Sintice* and *Biſaltia* lay towards the N. and N.E. of Creſtonia, upon the Pontus, between the mountains, and had a town named Heraclea Sintica. *Biſaltia* was a country inhabited by the Biſaltæ, who occupied a territory near the river Strymon. Another conſiderable part of Macedonia was comprehended in a peninſula, which projected between the Thermaic gulf to the weſt, and the Strymonic gulf to the eaſt. Towards the N.W. was the ſmall country called *Greſſæa*; ſouthwards from the ſea to the E. was Chalcidica, terminated by three long peninſulas, paſſing in a direction from N.W. to S.E. The moſt weſterly was called *Pallena*, which had formerly borne the name of *Phlegra*; the next was *Sithonia*; and the third was a peninſula joined to the continent by a tongue of land, in which was ſituated mount Athos. On the weſtern coaſt is *Croſſæa*, with its towns Ænia or Ænea, Gigonus, Smyla, Antigonea, Combrea, and Lipaxes or Lipaxus. Upon the iſthmus which connects *Pallena* with the continent, was the town called Potidæa, and afterwards Caſſandra; to the W. were the towns Sana, Menda, Scione, and Thrambus or Therambus. At the extremity of the S.E. was *Canaſtræum Promontorium*, together with a place of the ſame name. Upon the eaſtern coaſt were Æga and Aphitis. Between the eaſtern coaſt of *Pallena* and the weſtern coaſt of *Sithonia*, the ſea formed a gulf, called *Toronaicus Sinus*; at the bottom of this gulf, on an eminence, was the town of Olynthus, ſeparated from the gulf by the Bolyca palus, a marſh into which were diſcharged the two ſmall rivers Olynthius and Amnias. Upon the weſtern coaſt of *Sithonia* were the towns of Mecyberna, Sermyla, Galepſus, and Torone, whence the Toronaic gulf derived its name. At the weſtern extremity of this peninſula was the *Promontorium Derris*, and at the S.E. point was the *Promontorium Ampelos*. On the eaſtern ſide were Sarga, Singus, Pidaurus, and Aſſa, at the mouth of the Chabrius. The gulf, which bathed this coaſt, had taken its name from Singus, ſituated at the entrance of a very large bay. The peninſula, in which ſtood mount Athos, had ſeveral places ſituated along the ſea coaſt. On the coaſt towards the N. were Sana, Cleonæ, Thyſſum, near the *Promontorium Nymphæum*. Upon the coaſt towards the S.E. at the foot of the mountain, was Apollonia, and the promontory that bore the name of *Acro-Athos Promontorium*. Towards the N.W. were the towns of Olophyxus, Dium, and Acanthus, ſituated in a bay in which Xerxes would have brought his ſhips into the Singitic gulf when he meant to cut through Athos, in order to prevent the neceſſity and danger of doubling the two promontories, Acro-Athos and Nymphæum. To the N., on the ſame coaſt, are Stagyra, Arna, Arethuſa, Bromiſcus, Argilus, and Eion at the mouth of the Strymon, where alſo was Amphipolis.

The *Macedonia adjecta* of Cellarius, was that which was taken from Thrace in the time of Philip, and extended from the river Strymon on the W. to the Nyſſus on the E. Amphipolis, the port of which was Eion, belonged to this part. Cluverius places alſo in this part the town of Berga, but it really lay W. of the river. From Berga was derived the proverbial expreſſion Βεργαιζειν αντι τȣ μηδεν αληθες λεγειν, Bergaizare, id eſt, nihil veri dicere, for exaggeration, or ſaying any thing that was ſcarcely credible. To the E. of Strymon was Gazolus; on the ſea-coaſt, beyond Eion, were Phagres, Gapſelus, Æſyma, and Neapolis. In the inland territory was Philippi, formerly called Crenides and Datus, and which under its latter name became a Roman colony; and towards the W. Drabeſcus, Triuilum, Domerus, &c.

Macedonia was interſected by many Roman ways, the moſt ancient of which was called *Via Egnatia*. It was thought to have been a continuation of this Roman way, that terminated at Brundufium; it commenced at Dyrrachium, whence it paſſed by Hydrantum to Aulon, on the coaſt of Epirus. From each of theſe towns it branched off to Claudiana. From this place it paſſed to Lichnidus, belonging to the Daſſaretii, and thence turning to the S., it paſſed by Heraclea, belonging to the Lynceſtæ, by Edeſſa, Pella, Theſſalonica, Apollonia, Amphipolis, Philippi, Neapolis, and the reſt of Thrace, as far as Cypſelus or Cypſela on the Hebrus. Some authors have continued it as far as Conſtantinople.

Ptolemy extends Macedonia as far as the Ionian ſea, and aſſigns as its boundaries on the N. Dalmatia and Mœſia, and on the weſt Thrace. On the coaſt he places the Taulantii, then the Elymioti, Oreſtis, Edonis and Odomantice on the Strymonic gulf, and on the ſame gulf Amphaxitis, then Chalcidica, Paraxiæ on the coaſt, Pieriæ on the Thermaic gulf, the Pelaſgioti on the coaſt, Phthiotis on the Pelaſgic gulf; and northwards, towards the W., &c. the Albani, the Almopi, Orbellæ, the Eordati, the Eſtræi, Joranum, Sintices, the Daſſaretii, Lyceſtis, Pelagonia, Biſaltiæ, Mygdonia, Emathia, the Parthyæi, Stymphaliæ, the Eſtioti, and the Theſſalii. The iſlands which he aſſigns to Macedonia were Saſo in the Ionian ſea, and in the Ægean ſea, Lemnos with its two towns Myrina and Hephæſtia, Scixthos with a town of the ſame name, Scopelos, and Scyros with a town of the ſame name.

According to M. de l'Iſle's map of Greece, the extent of Macedonia from N. to S. was about 160 miles, and from W. to E. about 220. Its form was very irregular; but its ſituation was excellent, its ſhores being waſhed on the E. by the Ægean, and on the W. by the Ionian ſeas: but theſe advantages with regard to navigation and commerce, were never well improved; as the Macedonians were never powerful at ſea, notwithſtanding the many noble bays and excellent harbours which their coaſt afforded.

Among the moſt conſiderable mountains of this country, we may reckon the great ridge, which traverſed the northern part, called the Scardian mountains. In this part alſo was ſituated mount Pangæus, which was lofty and well covered with wood, and which was more valuable on account of its mines of gold and ſilver. From Thrace it was divided by mount Hæmus, which towards the W. joined the Scardian hills. Athos, in the Chalcidian region, was one of the moſt celebrated mountains in the world. (See ATHOS.) Olympus was alſo another mountain, that was ſo lofty as to reach almoſt the confines of heaven, whence the poets took the liberty of making it the ſeat of the gods. (See OLYMPUS.) The Scardian hills and mount Athos were well covered with woods; and, indeed, the whole kingdom of Macedonia, being every where intermixed with mountains and riſing grounds, abounded with all ſorts of trees, that were valuable on account either of timber, fruit, or ſhade. The ſeas that adjoined it were the Adriatic, which afforded ſeveral ſafe ports, beſides the great haven of Epidamnus, now Durazzo; and the Ægean ſea, which opened to this country not only the trade of Greece, but that of Aſia. Its bays were ſpacious, and four of them were eſpecially remarkable; *viz.* Sinus Strymonicus, which encloſed in its boſom the iſland of Thaſus, and is now called Golfo di Conteſſa:—Sinus Singiticus, having on one ſide mount Athos, and on the other a long ſlip of land, once full of rich and populous towns, now ſtyled Golfo di Monte Santo:—Sinus Toronaicus, having the ridge of land juſt mentioned on one ſide, and part of the region Paraxia on the other, now called Golfo di Aiomama:—and Sinus Thermæus, 60 miles in length, now called the gulf of Salonichi. Of the rivers of Macedonia, thoſe that fell into the Adriatic were the Panyaſus, the Apſus, the Laous, called alſo Æas and Aous, and Celydnus or Pepylichus, which is conſidered as the boundary between Macedon and Epirus. The rivers that diſcharged themſelves into the Ægean ſea were the Aliacmon, the Erigon, the Axius (ſee AXIUS), and the Strymon, the ancient boundary between Macedon and Thrace, but ſince the time of Philip this boundary has been the Neſſus. As to the lakes of Macedonia, beſides thoſe formed by the overflowing of the river Strymon, and the junction of the rivers Axius and Erigon, there is almoſt in the centre of the country, not far from the Candavian mountains, a large and famous lake, called the lake of Lychnidus, or the lake of Preſpa. There is alſo another lake in the province of Mygdonia; and a third near the ancient city of Sintia, called afterwards Heraclea Sintica.

The climate of Macedonia was ſalubrious and favourable to longevity; the ſoil was generally fertile, eſpecially on the ſea-coaſt, producing in abundance corn, wine, and oil; but the principal riches of Macedonia conſiſted in its mines of almoſt all kinds of metals, but more particularly of gold. The Romans, when they reduced Macedonia into a province, reſtrained the inhabitants from digging or refining gold or ſilver, but left them at liberty with regard to any other metal. In ancient times Macedonia abounded with horſes above all the other countries of Greece. Three hundred ſtallions, and 30,000 mares, were kept in the royal ſtud near Pella.

MACEDONIA, *Hiſtory of*. This country was originally inhabited by many nations. Thoſe from whom the race ſprang, which from ſmall beginnings became lords of Greece, were Argives. Under the conduct of Caranus, who was deſcended from Hercules by his ſon Temenus, they came into this country about 814 years B.C., and eſtabliſhed themſelves by their arms. Their dominion was afterwards conſiderably enlarged by their prudence as much as by their valour; for erecting no trophies after their victories, and treating thoſe whom they had ſubdued with the tenderneſs of brethren, they engaged the affections of the conquered, with whom they aſſociated as one people, and thus various tribes were reduced into one nation. Although the Macedonians were always governed by kings, they preſerved as great or even greater liberty than moſt of the Grecian commonwealths: their monarchs always ruling them according to the maxims of natural equity. This was the original conſtitution, and it may be ſaid, very much to their honour, that it was not ſubverted but with the kingdom. In caſes where the puniſhment was capital, the cauſe was heard by the army or by the people; and till they condemned the party, the king did not pretend to put him to death. Alexander in many inſtances adhered to this cuſtom; although a rigid regard to the conſtitution of his country was not always the ruling principle in a Macedonian monarch, as we are informed by Polybius. The throne was hereditary; and continued in the race of Caranus, till the ſlaughter of Alexander's family; and in general the eldeſt ſon ſucceeded. The ancient kings of Macedon made no oſtentatious diſplay of regal dignity. Alexander the Great was the firſt who wore a diadem and rich robes of ſtate, which were transferred to his ſucceſſors. The people were loyal and attached to their prince. With regard to marriage, the Macedonian kings were not very ſcrupulous; as they had frequently ſeveral wives and a number of concubines. In the education of their children they were very exemplary, their ſons being placed under the tuition of the beſt maſters, who inculcated the love and practice of great and glorious actions; and their daughters were initiated in the practice of every virtue. In the conduct of their own affairs they were moderate and prudent, affecting no magnificent entertainments, condeſcending to their ſubjects, and habituated to buſineſs. Their chief diverſion was hunting. Theſe princes were generally learned, or at leaſt patrons of learned men. In the moſt ſolemn acts of their adminiſtration, they maintained ſuch a decorum as rather endeared them to than awed their ſubjects. They heard cauſes in perſon, and ſuffered thoſe who pleaded before them to ſpeak with the greateſt freedom. After their deaths, the Macedonian kings were interred in the royal ſepulchre; and as they were beloved whilſt they lived, the people mourned for them when they died as for their common parents.

The Macedonians, with reſpect to religion, followed the opinions embraced by the reſt of the Greeks, worſhipping many gods, and indulging a great variety of ridiculous rites. Jupiter, Hercules, and Diana, were the objects of their ſpecial reverence. They were ſtrict in their morals, and temperate in their ordinary mode of living, but magnificent and ſelf-indulgent in their feaſts. At theſe feaſts no women were admitted; and it was an inviolable rule that nothing ſhould be divulged, that paſſed at their convivial meetings. They uſed their captives as concubines, but held it diſhonourable to marry them. In capital caſes, judgment was given by the voice of the army; in caſes of doubt torture was allowed; and their puniſhments were various. Sometimes, but chiefly on extraordinary occaſions, and in conformity to foreign cuſtoms, the criminal was thruſt through with darts, or crucified with his head downwards, or thrown chained into rivers; however, the moſt frequent puniſhment, and that which ſeems to have been legal, was ſtoning to death, in which the army, as they had been conſtituted judges, were executioners.

As there were ſeveral mines in Macedonia, there was under its ſeveral kings a variety of ſilver and gold coins; of the latter ſort were the Philippics, ſo called from bearing the buſt of Philip, the father of Alexander. Theſe were for a long time the moſt current coins in Greece.

The language of the Macedonians differed very much from the ſeveral dialects of the Greek; inſomuch that the natives of Greece, who ſerved in Alexander's army, were not able to underſtand a diſcourſe delivered in the Macedonian tongue.

Their military diſcipline deſerves particular notice, as it ſerved to raiſe them from being a mean and obſcure people to be lords of Greece. At firſt they were brave and warlike, and by degrees they became invincible from the union of ſuperior courage with military ſkill. Their army conſiſted of their natural born ſubjects, their allies, and mercenaries. The natives ſerved at their own expence, and contented themſelves with the ſpoil of their enemies. The allies were compoſed of the reſpective quotas of Theſſaly, Pæonia, and other dependent provinces, and of auxiliary troops furniſhed by Greece. The mercenaries were ſoldiers of fortune, who ſerved only for pay. The Theſſalians furniſhed horſe, and there were alſo many troops of Macedonian cavalry; the diſcipline of which was ſo ſtrict, that if any of the private men loſt their horſes, either by ſickneſs or in action, their officers were obliged to furniſh others out of their own ſtables. The infantry were compoſed of three bodies, *viz.* the light-armed, the peltaſtæ, who were better armed, and the heavy-armed ſoldiers, of whom the phalanx was compoſed. Theſe troops were adapted to all ſorts of enterpriſes. The heavy-armed foot were generally drawn up in the centre of the army, in a ſquare body, called the phalanx. This conſiſted, according to Polybius, of 16 in flank, and 500 in front, all pikemen, the ſoldiers ſtanding ſo cloſe, that the pikes of the fifth rank reached their points beyond the front of the battle. As to the arms of the Macedonians, they were offenſive and defenſive. At firſt their targeteers had only wooden bucklers, or ſuch as were made of a kind of wicker; but in proceſs of time, they had them of leather and braſs. Their ſwords, like thoſe of other Greeks, were made both for puſhing and cutting; and they alſo made uſe of daggers. Their ſpears were both long and ſhort; they had alſo breaſt-plates made of linen quilted to a proper thickneſs, and a particular kind of military ſhoe. When the army was in the field, the phalanx was drawn up generally in the centre. The horſe and light-armed troops in two lines on the right and left. Immediately before battle, the king or general uſually made an oration, of which the ſoldiers expreſſed their approbation by claſhing their arms; but if it did not affect them, they remained ſilent. When they charged, they exclaimed, Alala! Alala! and when they deſired quarter, they held their ſpears aloft in the air. All authors agree in repreſenting the hardineſs, frugality, and good order of the Macedonian troops. Their camp was always fortified with a good ditch and entrenchment. Their tents were ſmall, made of ſkins, and when folded up, they made uſe of them in paſſing rivers. The king's tent was pitched in the centre, and conſiſted of two rooms, one in which he ſlept and the other in which he ſaw company; and before the door of it, his guards did duty. The military ſignals of the Macedonians were either trumpets or fires. On a march the cavalry and light-armed troops took poſt in the van, the phalanx in the centre, and the baggage in the rear, unleſs they apprehended a ſudden engagement; in which caſe they marched in order of battle. Every ſoldier had a kind of knapſack, and the army was attended with a certain number of carts and waggons; but the Macedonians did not allow either women or uſeleſs ſervants to follow the camp. The plunder was ſometimes diſtributed among the ſoldiers, at other times collected and ſold for the uſe of the king, or for the army. In quarters, the army was preſerved from corruption, and its diſcipline maintained by military games, in which rewards, both honorary and lucrative, were beſtowed. After victories, the kings were accuſtomed to reward all who diſtinguiſhed themſelves.

Thoſe who died in the ſervice were honoured with public monuments, and their children and relations were freed from tribute. In all other reſpects, they were treated with the greateſt humanity and condeſcenſion; and when the time limited for their ſervice expired, or their wounds rendered them incapable of ſerving, they were diſmiſſed, with ample proviſion for themſelves and families, that they might enjoy the fruits of their labour, and by living in eaſe and peace, excite younger and more robuſt men to come cheerfully in their room.

The kingdom of Macedon commenced with Caranus in the year 814 B.C. and continued 646 years, till the battle of Pydna.

A Table of the kings of Macedon from its eſtabliſhment to its diſſolution.

B.C.	Kings.
814	Caranus.
786	Cænus.
774	Thurimas.
729	Perdiccas I.
678	Argæus I.
640	Philip I.
602	Æropas.
576	Alectus or Alcetas.
547	Amyntas I.
497	Alexander I.
454	Perdiccas II.
413	Archelaus, ſaid to be the patron of learning.
399	Amyntas II.
398	Pauſanias.
397	Amyntas II.
392	Argæus II. the Tyrant.
390	Amyntas II. reſtored.
371	Alexander II.
370	Ptolemy *Alorites*.
366	Perdiccas III.
360	Philip II. ſon of Amyntas.
336	Alexander III. called the Great.
323	Philip III. *Aridæus*.
316	Caſſander.
298	Antipater.
297	Alexander.
294	Demetrius *Poliocertes*.
287	Pyrrhus.
286	Lyſimachus
280	Ptolemy *Ceraunus*.
279	Meleager.
278	Antipater the *Eteſian*.
277	Antigonus, called *Gonatas*.
243	Demetrius II.
232	Antigonus *Doſon*.
221	Philip V.
179	Perſeus.
168	Perſeus defeated at the battle of Pydna, and taken priſoner by the Romans, which properly finiſhes the kingdom of Macedon.
152	Andriſcus, pretending to be the ſon of Perſeus, aſſumed the tyranny of Macedon, but died in the year 148 B.C.

In the preceding reigns no very intereſting event occurred, till that of Amyntas, to whom Megabyzus, the Perſian general, ſent ſeven of the principal commanders of his army to require him to acknowledge king Darius. Amyntas complied, and gave them a magnificent feaſt. Being intoxicated with wine, they deſired that the women might be produced according to the cuſtom of Perſia. In this particular they were alſo gratified; but as their intoxication increaſed, they began to behave in a brutal manner, and were all ſlain by the contrivance of Alexander, the ſon of Amyntas. Upon this Bubaris was ſent by Megabyzus, with a conſiderable body of troops, to revenge their deaths; but Alexander contrived to pacify Bubaris, by introducing to him Gygæa his ſiſter, who was a very beautiful woman; and who ſo far captivated the officer, that for the ſake of obtaining her for a wife, he adjuſted all things to the ſatisfaction of Amyntas. From this time the kings of Macedon became tributary to the Perſian emperors; but they were always regarded as faithful allies, and treated with kindneſs and reſpect. From this reign the hiſtory of the kings of Macedonia begins to be blended with that of the other powers of Greece. The Macedonian ſovereigns inſenſibly extended their poſſeſſions and authority both to the eaſt and weſt of their country; and the prudence of Perdiccas I. paved the way for the proſperous reign of Philip II., and for the ſucceeding conqueſts of his ſon Alexander. (See the biographical articles of Philip and Alexander *the Great.*) After a reign of about 12 years, the extenſive dominions of Alexander were divided among his generals; Philip Aridæus was recogniſed as his ſucceſſor; but the ambition of the other princes deprived him of a great part of his father's poſſeſſions. His ſucceſſors, after many deſtructive wars with the princes who reigned in Aſia, terminated their career by a war with the Romans, which proved diſaſtrous to them; ſo that Perſeus, after his defeat, was carried captive to Rome; and in a ſhort time Macedonia became a part of the Roman empire. See the next article.

Macedonia *Salutaris*. When Paulus Æmilius had finiſhed the conqueſt of Macedonia, by his victory over Perſeus its laſt king, he divided this kingdom into four diſtinct regions, which became ſubject to different ſorts of government, ſometimes at the will of the emperor, and at other times under the authority of the ſenate. At length, after the reign of Conſtantine, Macedonia became ſubject to the government of the prætorian prefect of the Eaſtern Illyria, and was divided into two provinces. The ſecond of theſe provinces was named *Salutaris*, on account of its mineral waters; it extended itſelf to the upper part of Macedonia, in the vicinity of the mountains which ſeparated this province from Mœſia Superior or Dardania. It was under the metropolis of Sobi, and compriſed eight towns. Pliny.

Macedonia, in *Modern Geography*, a province of European Turkey, bounded on the N. by Servia, on the E. by Romania, on the S. by Theſſaly and the Archipelago, and on the W. by Albania. Its figure is irregular; its ſituation advantageous; and the air clear, ſharp, and ſalubrious. The ſoil is, in general, fertile; and the maritime coaſts particularly abound with corn, wine, and oil. In the inland parts are ſeveral uninhabited waſtes. It had formerly mines and plenty of timber. Its numerous fine bays render it convenient for trade. Its capital is Salonichi. See the article Macedonia.

MACEDONIAN Kingdom, in *Ancient Hiſtory*, one of the four kingdoms into which the empire of Alexander was divided after his death. This kingdom, under Perſeus, who was overcome and taken by Æmilius, and carried in triumph to Rome, where he died in priſon, was reduced to the form of a Roman province. The other three, *viz.* the Aſiatic, Syrian, and Egyptian kingdoms, flouriſhed for a conſiderable time under their own kings, but were at laſt compelled to receive the Roman yoke.

Macedonian *Parſley*, in *Gardening*. See Bubon.

Macedonian *Year.* See Year.

MACEDONIANS, in *Eccleſiaſtical Hiſtory*, the followers of Macedonius, biſhop of Conſtantinople, who, through the influence of the Eunomians, was depoſed by the council of Conſtantinople in 360, and ſent into exile. He conſidered the Holy Ghoſt as a divine energy diffuſed throughout the univerſe, and not as a perſon diſtinct from the Father and the Son. The ſect of Macedonians was cruſhed before it had arrived at its full maturity, by the council aſſembled by Theodoſius in 381, at Conſtantinople. See Semi-arians.

MACEIRA, or Midjare, in *Geography*, an iſland in the Arabian ſea, near the coaſt, about 50 miles long, and from three to eight broad. It is barren and uninhabited, and on the N.W. coaſt are dangerous ſhoals, extending 90 miles along the ſhore, and far into the ſea, ſo that the land cannot be ſeen till the unſkilful pilot touches the rocks. N. lat. 20° 48'. E. long. 57° 35'.

Maceira, *Little*, an iſland in the Arabian ſea, 16 miles long and three broad; 10 miles W. of Maceira.

MACER, Æmilius, in *Biography*, a Roman poet, who flouriſhed in the age and reign of Auguſtus, and is mentioned as a writer in natural hiſtory. His works are referred to by Ovid, particularly a poem on the events of the Trojan war, after the period at which Homer concludes. A poem, "De Herbarum Virtutibus," extant under the name of Macer, is now given up as ſuppoſititious.

Macer, in *Geography*, a river of Africa, in the country of Tripoli, which runs into the Mediterranean.

Macer, in the *Materia Medica*. The Grecian macer is brought from Barbary; and the part in uſe is the thick yellow bark, which has a very aſtringent taſte, and is ſaid by Dioſcorides to be good againſt ſpitting of blood, the dyſentery, and fluxes. See Simarouba.

MACERATA, in *Geography*, a town of Naples, in Lavora; about three miles from Capua.—Alſo, a town in the marquiſate of Ancona, on the Chienta, the ſee of a biſhop, ſuffragan of Fermo; containing ſeveral churches, 13 convents, an univerſity, two academies, and about 10,000 inhabitants; 20 miles S. of Ancona. N. lat. 43° 15'. E. long. 13 31'.—Alſo, a town in the duchy of Urbino; 10 miles N.W. of Urbino. N. lat. 43° 48'. E. long. 12 35'.

MACERATION, in *Pharmacy*, the operation of diſſolving a ſolid body by means of water, or ſome other liquor.

In this ſenſe, the word amounts to much the ſame with liquefaction, or liquation.

Maceration is alſo uſed for the infuſing of a body in any menſtruous fluid, or in order to a ſolution of its principles, whether with or without fire.

In which ſenſe maceration amounts to much the ſame with digeſtion.

Others reſtrain maceration to that particular kind of digeſtion which is performed in thick ſubſtances, as when having mixed roſes with fat to make *unguent. roſatum*, the mixture is expoſed for ſome days to the ſun, that the virtue of the roſes may be the better communicated to the fat.

MACHA Mona, a kind of African calabaſh. It is the fruit of a very large tree which grows in Africa, and the American iſlands. When this fruit is ripe, the pulp has a ſouriſh taſte, with a little aſtringency: it is delicious in hot countries; and they prepare a liquor of it, which they uſe inſtead of lemonade, to cool and refreſh themſelves, and give it to ſick perſons under a looſeneſs. The pulp, dried, taſtes as well as the ſpiced bread of Rheims. The ſlaves make a kind of thick gruel with this pulp and water; it is of an abſorbent quality. The African women uſe the pulp inſtead of rennet, for curdling their milk.

The ſeeds of this fruit are as big as ſmall pine-apple kernels, kidney-ſhaped, of a cheſnut-colour, and encloſing an almond far more delicious than our ſweet almonds.

MACHACA, in *Geography*, a town of Peru, in the dioceſe of La Paz; 80 miles S.W. of La Paz. S. lat. 17° 40'. W. long. 69° 14'.

MACHÆRINA, in *Botany*, Vahl. Enum. v. 2. 238. See Schoenus.

MACHÆRION, a word uſed by chirurgical writers, as the name of an inſtrument of the nature of the inciſion knife. It is alſo ſometimes uſed to expreſs an inciſion; and by the aruſpices of old it was applied to ſome particular part of the liver of animals, from which they preſaged events.

MACHÆRUS, or Macheronte, in *Ancient Geography*, a city and fort beyond Jordan, in the tribe of Reuben, N. and E. of the lake Aſphaltites, two or three leagues from Jordan, and not far from its mouth in the Dead ſea. This caſtle had been fortified by the Aſmoneans. Gabinius demoliſhed it, and Ariſtobulus fortified it anew; and Herod the Great made great additions to its ſtrength. At or near it was a ſpring of very ſalutary hot waters. John the Baptiſt was put in priſon, and beheaded at Machærus, by the order of Herod Antipas. Joſephus Ant.

MACHALA, in *Geography*, a town of South America, in the audience of Quito, and juriſdiction of Guayaquil; annexed to the lieutenancy of Puna. It lies on the coaſt of Tumbez, together with that of Naranjol, the landing-place of the river of the ſame name, called alſo the Suya, near which is a road leading to the juriſdictions of Cuenca and Alauſi. The juriſdictions of Machala and Manaranjol produce great quantities of cacao, and that of the former is eſteemed the beſt in Guayaquil. In its neighbourhood, as well as in the iſland of Puna, are great numbers of mangrove-trees; in the wood of which the Indians pay their annual tribute. This wood is uſed in ſhips, &c. and is very durable, as it is ſubject neither to ſplit nor rot: 55 miles N.N.W. of Loxa. S. lat. 3° 15'. W. long. 79°.

MACHAON, in *Biography*, an illuſtrious hero and phyſician, who, with his brother Podalirius, accompanied the Grecian army in the expedition againſt Troy, and performed great ſervices among the troops. Theſe two perſons were deemed the ſons of Eſculapius; and Machaon appears to have been the elder brother, according to the poet Quintus Calaber, who introduces Podalirius as ſaying, on the occaſion of his death, that "his dear brother had brought him up like a ſon, after their father was taken into heaven, and had taught him to cure diſeaſes." (Lib. vii. v. 60.) Homer, indeed, mentions Podalirius firſt, when he names both together; but that ſeems to have ariſen only from the convenience of the verſe. Ποδαλείριος ἠδὲ Μαχάων. For Machaon appears to have been moſt highly eſteemed by the great officers of the army. It was he who adminiſtered to Menelaus, when wounded by Tindarus, firſt wiping the blood from the wound, and then applying emollient remedies, after the manner of his father. It was Machaon, alſo, who cured the lameneſs of Philoctetes, occaſioned by dropping an arrow, dipped in the gall of the Lernean Hydra, bequeathed him by

Hercules, on his foot. "Tarda Philoctetæ ſanavit crura Machaon." Prop. lib. ii.

It appears, too, from the writings of the poets, that Machaon was a brave and active ſoldier; for he is mentioned as engaged in ſome of the moſt dangerous enterpriſes, with the other celebrated leaders. Homer tells of a wound which he received in the ſhoulder, in one of the ſallies of the Trojans; and Virgil and Hyginus inform us, that he was one of the brave warriors who entered the wooden horſe, from which, according to the former, he was the firſt to deſcend. (Æneid. lib. ii. v. 263. Hygin. Fabul. lib. i. cap. 81. &c.) He is ſaid to have loſt his life in ſingle combat with Nereus, or, as others ſtate, with Eurypilus, the ſon of Telephus, during the ſiege of Troy; which, however, is inconſiſtent with the aſſertion juſt mentioned, ſince the ſiege was terminated by the introduction of the troops in the wooden horſe. (See Pauſanias in Laconic. 2. Calaber, lib. vi. & vii.) Pauſanias adds, that the remains of Machaon were preſerved by Neſtor, and conveyed to Meſſenia, where they were buried.

Machaon married Anticlea, daughter of Diocles, king of Meſſenia, by whom he had two ſons, Nichomachus and Gorgaſus, who reſided at Pheræ, and poſſeſſed the territory of their grandfather, until the Heraclidæ, on their return from Troy, made themſelves maſters of Meſſenia, and the reſt of the Peloponneſus. Machaon is ſuppoſed to have been a king, either in his own right, or that of his wife, ſince Homer, in two or three places, calls him "Paſtor of the people," (ποιμένα λαῶν), a title which he gives to Agamemnon and the other kings. Pauſanias mentions three other ſons of Machaon, namely, Sphyrus, Alexanor, and Polemocrates, who are ſuppoſed to have been the fruit of another marriage. M. Goulin, in his literary and critical memoirs, ſtates his opinion, that the birth of Machaon may be fixed about the year of the world 2765. See Le Clerc. Hiſt. de la Médecine. Schultzius Hiſt. Medicinæ.

MACHAU, Guillaume, a French poet and muſician, born about 1282. He was at firſt in the ſervice of the conſort of Philippe-le-Bel, and, in 1307, was appointed valet-de-chambre to the king, and continued to occupy this office to the end of that prince's reign, who died in 1314.

As the works of this author are the moſt ancient lyric compoſitions that have been preſerved in France, with the original muſic, great pains have been taken in commenting them, and rendering both words and muſic intelligible.

The abbé Lebœuf, in the year 1746, gave a very ample and ſatisfactory account to the Academy of Inſcriptions at Paris of two volumes of French and Latin poems, preſerved in the library of the Carmelites of that city, "with a deſcription of the kind of muſic to which ſome of theſe poems were ſet."

In 1747, the count de Caylus, having found in the king of France's library, N° 7609—2, a duplicate of theſe poems, gave likewiſe an account of them to the ſame Academy, in two memoirs. The author, Guillaume de Machau, is ſtyled by the count, *poet and muſician;* and both theſe excellent critics agree, that he flouriſhed about the middle of the fourteenth century, and died in 1370. Among the poems, which are written upon various ſubjects, there is an infinite number of lais, virelais, ballads, and rondeaux, chiefly in old French, with a few in Latin, and ſet to muſic: ſome for a ſingle voice, and others in four parts, triplum, tenor, contratenor, and a fourth part, without a name. In theſe full pieces, as the words are placed only under the *tenor part*, it is natural to conclude that this was the principal melody. In the muſic, which is written with great care and neatneſs, notes in a lozenge form, with *tails* to them, frequently occur; theſe, whether the heads were *full* or *open*, were at firſt called *minims;* but when a ſtill quicker note was thought neceſſary, the white or open notes only had that title, and the black were by the French called *noir*, and by Engliſh *crotchets:* a name give by the French with more propriety, from the hook or curvature of the tail, to the ſtill more rapid note, which we call a *quaver*.

The Latin poems are chiefly motets, and for a ſingle voice; ſome of which are written in black and red notes, with this inſtruction to the ſingers: "nigræ ſunt perfectæ, & rubræ imperfectæ." An admonition worth remembering by thoſe who wiſh to decipher muſic of the fourteenth and fifteenth centuries, in which red notes frequently occur. It was an eaſy expedient of diminution, till the invention of printing, when the uſe of ink of different colours, on the ſame page, occaſioned the expence and trouble of *double printing*. The abbé Lebœuf obſerves, that the diſſection and accelerated motion of notes, during theſe ages, gave great offence and ſcandal to pious and ſober Chriſtians. In a kyrie eleiſon to the Gregorian chant, which is called *tenor*, the three parts that are added to it are called triplum, motetus, and contratenor. In the ſecond volume of theſe poems the common chants of the whole maſs, and even the credo, are written in four parts. This maſs is ſuppoſed to have been ſung at the coronation of Charles V. king of France, 1364.

There are in the French MS. many ballads and rondeaux in three parts, tenor, triplum, and contratenor. The fourteenth century ſeems the era when muſic in parts, moving in different melodies, came firſt into general favour; for of the preceding age no muſic can be found of more than two parts in ſtrict counterpoint of note againſt note.

Machau calls his collection of ſongs ſet to muſic, *Remedes de fortune*, regarding muſic as a ſpecific, or at leaſt an opiate, againſt the ills of life. In the illuminations to theſe lyric compoſitions an aſſembly of minſtrels is repreſented with thirty or forty muſical inſtruments, of which he gives the names. His poem called "Le Dit de la Harpe," is a moral and allegorical piece in the ſtyle of the famous "Roman de la Roſe," by Guillaume de Loris, and Jean de Meun.

The abbé Rive has likewiſe given an hiſtorical and critical account of another MS. copy of thoſe poems in the collection of the duke de le Valliere; but none of theſe gentlemen have produced ſpecimens of Machau's muſical compoſitions; indeed the count de Caylus frankly confeſſes, that though he has ſtudied this muſic with the utmoſt attention, and conſulted the moſt learned muſicians, he has been utterly unable to ſatisfy his curioſity concerning their intrinſic worth.

Machau, in *Geography*, a town of Bohemia, in the circle of Konigingratz; eight miles S.W. of Branaw.

MACHAVANA, a river of Africa, which runs into the Indian ſea, S. lat. 26° 45′.

MACHAULT, James de, in *Biography*, a French Jeſuit, was a native of Paris, and born in 1599. He entered on his noviciate in his eighteenth year, and after having finiſhed the uſual courſe of academic ſtudies, he was ſelected to teach, firſt polite literature, then philoſophy, and for ſeveral years divinity, in different ſeminaries belonging to the order. He was elected ſucceſſively rector of the colleges at Alençon, Orleans, and Caen, and died in his native city in 1680. He was author of many conſiderable works, as "The Account of the Miſſions in Paraguay and other Parts of South America," 8vo. 1636; "A Relation of the State of Affairs in Japan," 1646; "Account of the Provinces of Goa," &c.; "A Relation of the Travels of twenty-five Members of the Society on the Indian Miſſion," 1659; "Account of the Miſſion of the Society in Perſia," &c.

Machault, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton, in the diſtrict of Vouziers; nine miles S.W. of Vouziers. The place contains 693, and the canton 4000 inhabitants, on a territory of 242½ kiliometres, in 14 communes.

MACHECOUL, a town of France, in the department of the Lower Loire, and chief place of a canton, in the diſtrict of Nantes; 18 miles S.W. of Nantes. The place contains 1899, and the canton 5152 inhabitants, on a territory of 155 kiliometres, in ſix communes. N. lat. 47°. W. long. 1° 44′.

MACHERA Lapis, in *Natural Hiſtory*, the name of a ſtone of a ferruginous colour, frequent on mount Berecynthus in Phrygia. Plutarch, and many other grave writers, relate, that if any perſon found this ſtone, and took it up at the time of the celebration of Cybele, he inſtantly was ſeized with madneſs.

MACHERIA, in *Geography*, a town of Hindooſtan, in Palnaud; ſix mile S.W. of Timerycotta. N. lat. 27° 35′. E. long. 77° 15′.

MACHERN, a town of Pruſſia, in Natangen; 25 miles S. of Raſtenburg.

MACHERRY, a town of Hindooſtan, in the country of Mewat; 70 miles S.S.W. of Delhi.

MACHESIN, or Machisin, a town of Aſiatic Turkey, in the province of Diarbekir; 105 miles S.E. of Raca.

MACHIA, a town of Naples, in the country of Moliſe; 12 miles S.W. of Moliſe.—Alſo, a town of Naples, in the Capitanata; 10 miles N.N.W. of Volturara.—Alſo, a town of Naples, in Calabria Citra; five miles N. of Biſignano.—Alſo, a town of Naples, in Principato Citra, on the coaſt; 15 miles S. of Capaccio.

MACHIAN, one of the Molucca iſlands, near the W. coaſt of Gilolo; about 18 miles in circumference, and populous. The Dutch have three forts garriſoned with ſoldiers. Its principal articles of commerce are cloves and ſago: a little N. of the line. E. long. 127° 21′.

MACHIANA, an iſland at the mouth of the river of the Amazons, about 15 miles long and three broad; a little S. of the line. W. long. 57° 2′.

MACHIAS, a port of entry, poſt-town, and ſeat of juſtice in Waſhington county, and ſtate of Maine, America, ſituated on a bay of the ſame name; 20 miles S.W. of Paſſamaquoddy, in N. lat. 47° 37′. This town carries on a conſiderable trade to Boſton and the Weſt Indies, in fiſh, lumber, &c. It was permanently ſettled in 1763, and incorporated in 1784. The chief ſettlements are at the E. and W. Falls, and at Middle river. At W. Falls, there is a gaol, and the county courts are held there. The entrance of Machias river is in N. lat. 44° 35′. W. long 66° 56′. The town is divided into four diſtricts for the ſupport of ſchools, and into two for the convenience of public worſhip. In 1792 Waſhington academy was eſtabliſhed here, which has for its ſupport a townſhip of land. In 1800 the town contained 1014 inhabitants. The exports conſiſt principally of lumber, *viz.* boards, ſhingles, clap-boards, laths, and various kinds of hewed timber. The cod-fiſhery, which might be proſecuted to advantage, has been neglected. The ſaw-mills are 17 in number, and much employed. The total amount of exports annually exceeds 15,000 dollars. From Machias bay to the mouth of St. Croix there are many fine iſlands. Morſe.

MACHIAVELISM, in *Literary Hiſtory*, is a ſpecies of deteſtable politics, which may be defined in few words, the art of reigning tyrannically, the principles of which are inculcated in the works of Machiavel, a native of Florence, and particularly in his treatiſe, entitled "The Prince." M. de Wicquefort obſerves, concerning the character of this writer: Machiavel ſays almoſt every where what princes do, and not what they ought to do. To the ſame purpoſe the chancellor Bacon remarks: "Eſt quod gratias agamus Macchiavello et hujus modi ſcriptoribus qui aperte & indiſſimulanter proferunt quid homines facere ſoleant non quid debeant." Machiavel was ſecretary, and afterwards hiſtoriographer to the republic at Florence. He was put to the rack upon the ſuſpicion of being concerned in a confederacy againſt the houſe of Medicis; but he endured the torments of it, without making any confeſſion. He was as much an enemy to religion as to ſound politics; and is ſaid to have died in the year 1530, uttering profane jeſts and blaſphemies. Bayle. See Macchiavelli.

MACHIAWARA, in *Geography*, a town of Hindooſtan, in the circar of Sirhind; 28 miles N. of Sirhind.

MACHICOLATION, from *meche*, a match or wick to preſerve fire, and *couler*, to flow, in *Fortification*, perpendicular apertures in the upper part of the gate of an ancient caſtle, for the purpoſe of pouring down various burning ſubſtances on the aſſailants, when they were battering them, or otherwiſe trying to force them open. In various ancient charters, permiſſion was granted to the owners of caſtles, *embattelandi*, *kernellandi*, and *machicolandi*.

MACHICORA, in *Geography*, a river of Madagaſcar, which gives name to a province, and runs into the ſea on the S. coaſt. S. lat. 25° 3′. E. long. 41° 12′.

MACHIGASTA, a town of South America, in the province of Tucuman; 50 miles W.S.W. of St. Fernand.

MACHINE, in a general ſenſe, ſignifies any thing that is uſed to augment or to regulate moving forces or powers; or, it is any inſtrument employed to produce motion, ſo as to ſave either time or force. The word is derived from *μηχανη*, *machine*, *invention*, *art*; and is therefore properly applied to any agent in which theſe are combined, whatever may be the ſtrength or ſolidity of the materials of which it is compoſed. The term machine, however, is by common uſage generally reſtricted to a certain claſs of agents, which ſeem to hold a middle place between the moſt ſimple *organa*, commonly called tools or inſtruments, and the more complicated and powerful, termed *engines*. This diſtinction, however, does not enter into the preſent article; we ſhall conſider machines under two heads, *ſimple* and *compound*. To the firſt claſs belong the *lever*, the *inclined plane*, the *ſcrew*, the *wedge*, the *wheel* and *axle*, and the *pulley*, commonly called the ſix mechanical powers; though ſome authors will only allow the lever, and the inclined plane, to be ſimple machines, the others being compounded of thoſe two.

Compound machines are all ſuch as conſiſt of a combination of the ſeveral ſimple machines or mechanical powers above-mentioned, the number of which in the preſent advanced ſtate of the ſciences is almoſt infinite. Theſe are again claſſed under different denominations, according to the agents by which they are put in motion, the purpoſes they are intended to effect, or the art in which they are employed, as hydraulic, pneumatic, military, architectural, &c. machines. The ancients excelled in the two latter ſpecies of engines, but in thoſe which relate to civil arts and manufactory, the moderns have doubtleſs far exceeded their maſters. With regard to military machines, the invention of gunpowder has completely changed their nature, and all thoſe of the ancients are become uſeleſs and forgotten; theſe were principally of three diſtinct ſpecies, *viz.* thoſe employed for throwing deſtructive weapons; as the *ſcorpion*, which was for caſting arrows; the *catapulta* for ſtones and javelins; the *pyrobole* for flaming darts; the *balliſta* for bullets, &c. &c.

Others were for razing the walls of fortified places, of which the principal was the *aries*, or *battering ram*; and thoſe of the third kind were for covering the approaches of the beſiegers, as the wooden tower, &c.; for a deſcription of which ſee the reſpective articles. The warlike machines employed by Archimedes in the defence of Syracuſe have been much applauded by the ancients, and though many of the circumſtances related on this head are doubtleſs falſe or exaggerated, yet it is ſufficient to know the genius of their author to be convinced that they were powerful and effective, probably much exceeding any of thoſe of which the conſtruction has been aſcertained.

Of the architectural machines of the ancients we are totally unacquainted, and one is at a loſs to conceive what means they employed for tranſporting and raiſing thoſe enormous ſtones which are found in the walls of ſome ancient buildings, though it is not unlikely that they owed as much to their patient perſeverance and manual labour, as to the power of their machines. The Spaniards, when they made the conqueſt of Peru, were ſtruck with aſtoniſhment to find the natives, whom they conſidered as ſavages and barbarians, raiſing enormous maſſes of ſtone of ten feet ſquare for building walls and other purpoſes, without the aſſiſtance of any inſtruments than thoſe which nature had ſupplied them with: unacquainted with any other ſcaffolding but that of banks of earth raiſed againſt their buildings, they contrived by ſtrength of hand to raiſe theſe maſſy loads up the inclined planes thus formed; and many of the Druidical remains in this country were probably erected in a ſimilar manner. The ancient Greek and Roman architects, however, were no doubt acquainted with, and employed very powerful machines in the conſtruction of their noble edifices, with the nature of which we have not been informed; even Vitruvius, who writes expreſsly on the ſubject, has left us nothing that can throw any light on the conſtruction of theſe engines, yet that they were in poſſeſſion of immenſe and wonderful machinery, appears in the moſt convincing manner to any perſon who reflects on the magnificent ſtructures which they erected, and which excite to this day the wonder and admiration of the world, not only on account of their grandeur and incomparable elegance, but alſo on account of the mechanical knowledge that ſeems indiſpenſably neceſſary for their erection.

The hydraulic machines of the ancients were indeed much inferior to thoſe of modern invention. The *ſcrew* of Archimedes, and the *pumps* of Cteſibius, were the principal engines of this deſcription; for which ſee the reſpective articles. As to the modern machines they are too numerous to admit even of a ſlight enumeration in this place; moſt of them, however, of any importance, will be found under the ſeveral heads in this work. See Cranes, *Wind* and *Water* Mills, Steam *Engine*, &c. &c.

Montucla, at the concluſion of the third volume of his "Hiſtoire des Mathematiques," has given a catalogue of ſeveral intereſting works, which have been compiled in order to deſcribe and exhibit the moſt important and curious machines, both ancient and modern, of which we have ſelected a few for the information of thoſe who may not poſſeſs the above-mentioned work.

1. The firſt and moſt intereſting modern work of this deſcription is entitled "Le diverſe et artificioſe machine del capitano Agoſtino Ramelli dal ponte della Treſia, &c. &c. compoſte in lingua Italiana et Franceſe; a Parigi 1588," in folio, (in Germany,) in 1620. This is a very ſcarce work, ſeldom to be met with but in choice libraries.

2. "Machinæ novæ Fauſti Verantii cum declaratione, Latina, Italica, Hiſpanica, Gallica, et Germanica," Venetiis 1591, 1625, in folio, with figures.

3. "Récueil de pluſieurs Machines militaires, &c. pour la Guerre et Récreations," par François Thypourel et Jean Appus, 1620, 4to.

4. "Heinrich Zeizings, Theatrum machinarum," Leipſic 1621.

5. "A Century of Inventions, &c." by Edward Somerſet, marquis of Worceſter, London 1663, in 12mo.

6. "Les dix Livres d'Architecture de Vitruve, &c." tranſlated into French by Claude Perrault, 1673, folio.

7. "Veterum mathematicorum, Athenaci, Apollodori, &c." 1693, folio. This learned and curious edition of the ancient Greek machinicians was begun by Thevenot, and finiſhed by La Hire; but it relates principally to military engines.

8. "Theatrum machinarum univerſale, &c." by Jacob Leupold, Leipſic, ſeven volumes folio, 1724, 1727, 1774. This is the greateſt and moſt complete work of the kind that ever was publiſhed. The firſt volume is little more than an introduction to the work; the ſecond and third volumes contain deſcriptions of hydraulic machines; the next two volumes relate to machines for raiſing weights, the theory of levelling, and other ſubjects; and the ſixth treats principally on machines connected with the conſtruction of bridges; the ſeventh volume is entitled "Théatre arithmetico geometrique," where the author treats of all inſtruments employed in theſe two ſciences. This work would have been much more conſiderable, if its author had lived to complete the immenſe taſk he had undertaken.

9. "A ſhort Account of the Methods made uſe of in laying of the Foundation of the Piers of Weſtminſter Bridge," by Charles Labelye, 1739.

10. "The Advancement of Arts, Manufactures, and Commerce; or, A Deſcription of uſeful Machines and Models," by A. M. Bailly, London 1778, 1779, folio.

Beſides the above-mentioned works, many uſeful particulars may be gathered from Strada, Beſſon, Beroaldus, Bockles, Beyer, Lempergh, Van Zyl, Belidor's Architecture hydraulique, Deſaguliers's Courſe of experimental Philoſophy, Emerſon's Mechanics. The Royal Academy of Sciences at Paris have alſo given a collection of machines and inventions approved of by them. This work, publiſhed by M. Gallon, conſiſts of ſix volumes in quarto, containing engraved repreſentations of the machines, with their deſcriptions annexed.

We might have carried the enumeration of works of this kind to a much greater length, but the above are the moſt intereſting, and the reader who wiſhes for farther information on this ſubject may conſult the hiſtory of Montucla abovementioned. But we ought not to omit to mention in this place, the ſecond volume of the "Architecture Hydraulique" of Prony, and the ſecond volume of Gregory's Mechanics: the firſt of theſe relates principally to ſteam engines, but the latter contains a deſcription of the moſt uſeful modern machines for various purpoſes.

In the conſtruction of machinery, as alſo in eſtimating its effects, ſeveral important conſiderations naturally ariſe in the mind of a ſkilful artiſt, ſuch as the effect of Friction, Rigidity of *ropes*, the Strength and Stress of materials; the proper meaſure, compariſon, and equilibrium of Forces, the laws of Rotatory and Accelerated *motion*, &c. &c. Theſe are all treated of under the reſpective articles in the Cyclopædia, and it therefore only remains for us in this place to offer a few remarks on the nature of machines in general, and the beſt means of determining their maximum effects.

Machines are introduced for three purpoſes, *viz.* to accommodate the direction of the moving force to that of the reſiſtance to be overcome; to increaſe the effect of a given finite power, ſo as to overcome a reſiſtance which is greater, and would otherwiſe ever remain unchanged: and laſtly, to regulate and modify a variable force, ſo as to produce a conſtant and uniform effect. Theſe are the principal ends to be accompliſhed by machines, and the experienced engineer will always endeavour to execute them in the ſimpleſt manner poſſible; for complicated machinery is not only moſt liable to inaccurate adjuſtment, and frequent diſarrangement, but is likewiſe more cumberſome and expenſive, at the ſame time that the retardation ariſing from friction, adheſion, and inertia, is more conſiderable, and conſequently a greater power becomes neceſſary, in order to produce the ſame effect. Another important point to be attended to, is the moſt advantageous application of the firſt mover, whether this agent be air, water, ſteam, or animal ſtrength. To enter upon this queſtion in all its generality, would far exceed our limits; beſides, with regard to the three former, they will be better inveſtigated under the articles *Wind* and *Water* MILLS, STEAM *Engine*, &c.; what few remarks, therefore, we have to make on this head, will be confined to the application of animal exertion to the motion of machines, and for the other agents we muſt refer the reader to the articles above-mentioned.

We have a ſtriking inſtance of the injudicious application of the exertion of men, in the old crane worked by means of an internal walking wheel, which, from its nature, muſt be very heavy, while the action of the man is exerted at a very trifling diſtance from the axle, and conſequently at a great mechanical diſadvantage; whereas in Hardie's crane, the man acting externally at the greateſt diſtance from the fulcrum, produces a much greater effect with leſs expence of labour; the other advantages which this machine poſſeſſes over the one above-mentioned, not ariſing ſolely from this cauſe, are not connected with our preſent enquiry.

The above remark applies principally to the mechanical advantage to be obtained in the application of a firſt mover; but there is alſo another conſideration of a phyſical nature, which is equally important, and ought therefore to be particularly attended to. No animal can exert more than a determinate and limited force; and, conſequently, if it requires all this force merely to produce an equilibrium, no effect will reſult from the action: and, on the other hand, if all the ſtrength of a man or horſe is employed in giving motion to himſelf, or to external objects before the application reaches the reſiſtance, there is ſtill the ſame unproductive effect. A man, for example, puſhing at a capſtan bar, muſt firſt of all walk as faſt as the bar moves round, which evidently requires an expenditure of his muſcular power; but this alone will not render his exertion effective: he muſt alſo preſs the bar forward, with as much force as he has remaining above that which he expended in walking at that rate. The proportion of theſe two expenditures may be very different under different circumſtances; and on the judicious ſelection of ſuch circumſtances as make the firſt of theſe as ſmall as poſſible, lies much of the ſkill of the engineer. In the common operation of thraſhing corn, much more than half the man's power is expended in giving the neceſſary motion to his own body; and only the remainder is employed in urging forward the ſwiple with a momentum ſufficient for ſhaking out the ripe grains from the ſtalk. Dr. Robiſon mentions an experiment, made in order to aſcertain the quantity of power thus loſt. In order to which, the ſwiple was taken off the flail, and the ſame weight of lead put on the end of the ſtaff; then by cauſing the labourer to perform the uſual motions of thraſhing, with all the rapidity that he could continue during the ordinary hours of work; it was found that the number of motions thus made was to thoſe made in the actual operation of thraſhing, in about the ratio of 3 to 2: whence we may infer, that at leaſt half the thraſher's power is expended in merely moving his own body. We may alſo bring another very ſimple caſe, by way of further illuſtration. Suppoſe a quantity of earth is to be removed from one place to another by barrows. It is obvious that the loads may be ſo great, that a man muſt exert his whole ſtrength barely to lift up the ſhafts, and conſequently will have none left to puſh the barrow forward: if part of the load be taken off, he can go forward, and ſo much the faſter as the quantity of the load is reduced; but if even the whole be taken away, he can ſtill only move at a certain rate, and, conſequently, in neither of the extreme caſes is any effect produced. It becomes then an intereſting queſtion to determine what load he ought to carry, in order to produce the greateſt poſſible effect in a given time. We ſhall not, in this place, enter any farther upon this ſubject, truſting that what has been already advanced will be ſufficient to point out the neceſſity of attending to ſuch circumſtances; and in the ſubſequent part of the preſent article, we will endeavour to explain in what manner the proper adjuſtment of power and effect may be computed.

The nature of the firſt movement being determined, the next object is to communicate it to the deſtined point, where the reſiſtance is to be overcome; and much of an artiſt's ſkill depends upon performing this in the ſimpleſt and moſt effectual manner poſſible. In order to this, it frequently becomes neceſſary to convert one ſpecies of motion into another ſpecies: as, for example, a rotatory into a reciprocating motion, or a reciprocating into a rotatory motion, &c. &c. The methods of forming this communication are extremely numerous, and it will not therefore be expected that we ſhould attempt an enumeration of them. In ſome inſtances, a ſimple lever or unbent cord will anſwer better than any combination; in others, it is highly advantageous to uſe a combination of levers acting upon each other by means of ſo many fulcra, and by which the direction of the motion may be changed at pleaſure; in others, as when motion is communicated to a ſeries of wheels and axles in ſucceſſion, it may be effected by a rope running in grooves round one wheel and the ſucceeding axle, or by means of tooth and pinion work, by a barrel and endleſs ſcrew, and various other contrivances which will naturally ſuggeſt themſelves, according to the circumſtances under which they ariſe.

This part of the conſtruction being ſettled, other important circumſtances require particular attention, *viz.* to adjuſt the ſeveral parts of the machine ſo, that its motion may be eaſy, free, and uniform. One of the moſt obvious methods of rendering a motion uniform is by means of a *pendulum* and *ſcapement* (ſee theſe two articles); and where theſe cannot conveniently apply, a fly is ſometimes employed; for a particular deſcription of which, ſee FLY. The uniformity of a machine is not, however, wholly dependent upon the application of ſuch regulators: there are other points connected with this ſubject, that muſt not be overlooked, and on which we intend to offer a few remarks; availing ourſelves, for this purpoſe, of the obſervations of Dr. Robiſon. When heavy ſtampers are to be raiſed, in order to drop on the matters to be pounded, the wipers by which they are lifted ſhould be made of ſuch a form, that the ſtamper may be raiſed by a uniform preſſure, or with a motion almoſt perfectly uniform: if this is not attended to, and the wiper is merely a pin ſticking out from the axis, the ſtamper is forced into action at once, which occaſions violent jolts to the machine, and great ſtrains on its moving parts, and their points of ſupport; whereas, when they are gradually lifted, the inequality of the motion is never felt at that point of the machine where the power is applied. We have ſeen, ſays the profeſſor, piſtons moved by means of a double rack on the piſton rod, where a half wheel takes hold of one rack, and raiſes it to the required height; and the moment the half wheel has quitted that ſide of the rack, it lays hold of the other ſide, and forces the piſton down again. This was conſidered as an improvement of the common method of the crank, by correcting the unequable motion of the piſton. But in fact it is far inferior to the latter, as it occaſions ſuch abrupt changes of motion, that the machine is ſhaken and torn to pieces with the jolts it occaſions; a circumſtance which will always be avoided as much as poſſible by a judicious engineer.

When ſeveral ſtampers, piſtons, or other reciprocal movers, are to be raiſed and depreſſed, their times of action ought to be diſtributed in a uniform manner, ſo that the machine may always be equally loaded with work. When this is done, and the obſervations in the preceding paragraph attended to, the machine may be made to move almoſt as ſmoothly as if there were no reciprocations on it. Nothing ſhews the ingenuity of the conſtructor more than the artful, yet ſimple, contrivances for obviating thoſe difficulties that unavoidably ariſe from the very nature of the work that muſt be performed by the machine, and of the power employed. We mentioned, above, the converſion of the continued rotation of an axis into the reciprocating motion of a piſton, and the improvement that was thought to have been made in the common and obvious contrivance of the crank, but which, as was obſerved, occaſioned ſuch jolts as would in a ſhort time have deſtroyed the machine. In order to avoid this, in a large forge where a great ſledge hammer of ſeven hundred weight was to be raiſed, the engineer formed the wipers into ſpirals, which communicated motion to the hammer almoſt without any jolt whatever: and under ſome circumſtances, this contrivance would have been highly beneficial; but in the machine to which we allude, it would not apply, as it did not communicate a ſufficient momentum to the hammer in its deſcent: yet it is deſerving of notice, as it might in ſome caſes become extremely advantageous.

In employing a power, which of neceſſity reciprocates, to drive machinery, in which a rotatory motion is required, as in applying the ſteam-engine to a cotton or griſt-mill, conſiderable difficulties alſo ariſe, which muſt be attended to with particular care. The neceſſity of reciprocation on the firſt mover waſtes much power, becauſe the inſtrument that communicates ſuch immenſe force muſt be extremely ſtrong, and well ſupported. The impelling power is waſted in imparting, and afterwards deſtroying, a great quantity of motion in the working beam. The ſkilful engineer will attend to this, and do his utmoſt to procure the neceſſary ſtrength of the firſt mover, without making it a vaſt load of inert matter: he will alſo remark that all the ſtrains on it, and on its ſupports, are changing their direction on every ſtroke; which therefore requires particular attention in the manner of ſupporting it. If we obſerve ſteam-engines that have been long erected, we ſhall find that they have uniformly ſhaken the building to pieces, which is principally to be attributed to the inattention of the engineer to this circumſtance; and experience has now taught us, that no building can long withſtand the deſultory and oppoſite jolts of ſuch immenſe maſſes; and, cenſequently, that the great movements ought to be ſupported by a frame-work, independent of the building which contains it. Another circumſtance, on which the uniformity of the motion depends, is the form given to the teeth of the wheel: this is of great importance, and has excited great attention amongſt both theoretical and practical machinicians. Two forms have been propoſed: of theſe the firſt was given by La Hire, who affirmed that the preſſure would be uniform, if the teeth were formed into epicycloids; and M. Camus, in his "Cours de Mathematique," has adopted and purſued La Hire's principle, and applied it to the various caſes that are likely to ariſe in practice. This conſtruction, however, is liable to a limitation; on which account, a ſecond method has been propoſed, which ſecures the perfect uniformity of motion, without any ſuch limitation. This conſiſts of making both teeth portions of involutes of circles; but as we ſhall conſider this ſubject under the articles TOOTH and PINION *Work*, it will be uſeleſs to inſiſt any farther upon it in this place; and we will therefore proceed to the theoretical inveſtigation of the power of machines, and their maximum effects; limiting our obſervation to thoſe principally whoſe motion is uniform, theſe forming by far the moſt numerous claſs, and the knowledge of which is, therefore, of the greateſt importance.

Of the maximum Effects of Machines.—When forces acting in contrary directions, or in any ſuch directions as produce contrary effects, there is with reſpect to every ſimple machine, and conſequently with reſpect to every compound one, a certain relation between the powers and the diſtances at which they act, which, if ſubſiſting in any ſuch machine when at reſt, will preſerve it in that ſtate of ſtatical equilibrium; becauſe the efforts of theſe powers, when thus related with regard to magnitude and diſtance, being equal and oppoſite, deſtroy each other, and have no tendency to change the ſtate of the ſyſtem to which they are applied. So alſo, if the ſame machine have been put into a ſtate of uniform motion, whether rectilinear or rotatory, by the action of any power diſtinct from thoſe we are now conſidering, and theſe two powers be made to act upon the machine in ſuch motion, in a ſimilar manner to that in which they act upon it when at reſt, their ſimultaneous action will preſerve it in that ſtate of uniform motion, or dynamical equilibrium, and this for the ſame reaſon as before; becauſe their contrary effects deſtroy each other, and have, therefore, no tendency to change the ſtate of the machine. But if at the time a machine is in a ſtate of balanced reſt, any one of the oppoſite forces be increaſed, while it continues to act at the ſame diſtance, this exceſs of force will diſturb the ſtatical equilibrium, and produce motion in the machine; and if the ſame exceſs of force continues to act in the ſame manner, it will, like every conſtant force, produce an accelerated motion; or if it ſhould undergo particular modifications, when the machine is in different poſitions, it may occaſion ſuch variations as will render it alternately accelerated and retarded. Or, the different ſpecies of reſiſtance to which a moving machine is ſubjected, as the rigidity of cords, friction, reſiſtance of the air, &c. may ſo modify it, as to change a regular or irregular variable motion into one which is uniform. Hence, then, the motion of machines may be conſidered as of three kinds, as that which is gradually accelerated, which obtains commonly in the firſt inſtants of the communication. 2. That which is entirely uniform. 3. That which is alternately accelerated and retarded. Pendulum clocks and machines that are moved by a balance are related to the third claſs. Moſt other machines are of the ſecond claſs, at leaſt a ſhort time after their motion is commenced.

Now, although the motion of a machine be alternately accelerated and retarded, it may, notwithſtanding, be meaſured

ſured by an uniform motion, in conſequence of the periodical and regular repetition which may exiſt in the acceleration and retardation. Thus, the motion of a ſecond pendulum, conſidered in relation to a ſingle oſcillation, is accelerated during the firſt half ſecond, and retarded during the ſecond; but the ſame motion taken for many oſcillations may be conſidered as uniform. Suppoſe, for example, that the extent of each oſcillation is five inches, and that the pendulum has made ten oſcillations; its total effect will be to have run over 50 inches in 10 ſeconds, and as the ſpace deſcribed in each ſecond is the ſame, we may compare the effects to a moveable, which moves for 10 ſeconds at the rate of five inches *per* ſecond. We ſee, therefore, that the theory of machines, whoſe motions are uniform, conduces naturally to the eſtimation of the effects of thoſe whoſe motion is alternately accelerated and retarded, ſo that what follows will be directed to thoſe machines only, whoſe motion falls under the ſecond head, ſuch problems being of far the greateſt utility in practice.

We have had already frequent occaſion to make uſe of the terms *mover*, or *moving force* and *reſiſtance;* and in what follows, they will be uſed in the ſame general ſenſe. By the firſt is always to be underſtood any cauſe of motion whatever, and by the latter, any thing that is oppoſed to the action of the former. The *impelled point* of a machine, is that to which the action of the moving power may be conſidered as immediately applied; and the *working point* is that where the reſiſtance ariſing from the work to be performed immediately acts, or to which it ought all to be reduced. Thus in the wheel and axle, *Plate* I. *fig.* 6. *Mechanics*, where the moving power P is to overcome the weight or reſiſtance W, by the application of the cord to the wheel and to the axle, A is the impelled point, and E the working point. The *velocity of the moving power* is the ſame as the velocity of the impelled point; and the *velocity of the reſiſtance*, the ſame as that of the working point. The *performance* or *effect* of a machine, or the *work done*, is meaſured by the product of the reſiſtance into the velocity of the working point; and the *momentum of impulſe* is meaſured by the product of the moving force into the velocity of the impelled point.

Theſe definitions being eſtabliſhed, we may exhibit a few of the moſt uſeful problems relative to the effect of machines, and with which we muſt conclude this article.

Let A B (*Plate* XXXII. *Mechanics*, *fig.* 1.) repreſent the velocity of a ſtream, A C the velocity of the part of the engine which it ſtrikes, when the motion of the machine becomes uniform, and C B will repreſent their relative velocity, upon which the effect of the engine depends. It is known that the action of a fluid upon a given plane, is as the ſquare of this relative velocity; conſequently the weight raiſed by the engine, when its motion becomes uniform, being equal to this action, it is likewiſe as the ſquare of C B. Let this be multiplied by A C, the velocity of the part of the engine, impelled by the fluid; and the effect of the engine in a given time will be proportional to $A\,C \times C\,B^2 =$ (ſuppoſing C B to be biſected in D) $A\,C \times 2\,C\,D \times 2\,D\,B = 4\,A\,C \times C\,D \times D\,B$; conſequently, the effect of the engine is greateſt when the product of A C, C D, and D B is greateſt. But it is eaſy to ſee, that this product is greateſt when the parts A C, C D, and D B, are equal; for if you deſcribe a ſemicircle upon A D, and the perpendicular C E meet the circle in E, then $A\,C \times C\,D = C\,E^2$, and is greateſt when C is the centre of the circle; ſo that in order that $A\,D \times C\,D \times D\,B$ may be the greateſt poſſible, A D muſt be biſected in C; and C B having been biſected in D, it follows that A C, C D, D B, muſt be equal; or that A C, the velocity of the part of the engine impelled by the ſtream, ought to be but one-third of A B, the velocity of the ſtream. In this caſe, when, (abſtracting from friction) the engine acts with the utmoſt advantage; the weight raiſed by it is to the weight that would juſt ſuſtain the force of the ſtream, as the ſquare of C B, the relative velocity of the engine and ſtream, to the ſquare of A B, which would be the relative velocity, if the engine was quieſcent; that is, as 2×2 to 3×3, or 4 to 9. Therefore, that the engine may have the greateſt effect poſſible, it ought to be loaded with no more than $\frac{4}{9}$ths of the weight, which is juſt able to ſuſtain the efforts of the ſtream. See Maclaurin's Account of ſir Iſaac Newton's Diſcoveries, p. 171, and Fluxions, art. 908.

Again, ſuppoſe that a given weight P, (*fig.* 2.) deſcending by its gravity in the vertical line, raiſes a greater weight W, likewiſe given, by the rope P M W, (that paſſes over the fixed pulley M) along the inclined plane B D, the height of which B A is given; and let it be required to find the poſition of this plane, along which W will be raiſed in the leaſt time, from the horizontal line A D to B. Let B C be the plane upon which, if W was placed, it would be exactly ſuſtained by P; in which caſe, P is to W as A B to B C. But W is to the force with which it tends to deſcend along the plane B D, as B D to A B; conſequently the weight P is to that force, as B D to B C. Therefore the exceſs of P above that force (which exceſs is the power that accelerates the motion of P and W) is to P, as $B\,D - B\,C$ to B D; or taking B H upon B C equal to B D, as C H to B D. But it is known that the ſpaces deſcribed by motions uniformly accelerated, are in the compound ratio of the forces which produce them and the ſquares of the times; or, that the ſquare of the time is directly as the ſpace deſcribed in that time, and inverſely as the force; conſequently, the ſquare of the time in which B D is deſcribed by W, will be directly as B D, and inverſely as $\frac{C\,H}{B\,D}$, and will be leaſt when $\frac{B\,D^2}{C\,H}$ is a minimum; that is, when $\frac{B\,C^2}{C\,H} + C\,H + 2\,B\,C$, or (becauſe $2\,B\,C$ is invariable) when $\frac{B\,C^2}{C\,H} + C\,H$, is a minimum. Now as when the ſum of two quantities is given, their product is a maximum when they are equal to each other; ſo it is manifeſt, that, when their product is given, their ſum muſt be a minimum when they are equal. Thus it is evident, that as in *fig.* 1, the rectangle or product of the equal parts A C and C D was equal to $C\,E^2$; ſo the rectangle of any two unequal parts, into which A D may be divided, is leſs than $C\,E^2$, and A D is the leaſt ſum of any two quantities, the product of which is equal to $C\,E^2$. But the product of $\frac{B\,C^2}{C\,H}$ and C H is $B\,C^2$, and conſequently given: therefore the ſum of $\frac{B\,C^2}{C\,H}$ and C H is leaſt when theſe parts are equal, that is, when C H is equal to B C, or B D equal to 2 B C. It appears, therefore, that when the power P and weight W are given, and W is to be raiſed by an inclined plane, from the level of a given point A to the given point B in the leaſt time poſſible; we are firſt to find the plane B C, upon which W would be ſuſtained by P, and to take the plane B D double in length of the plane B C; or we are to make uſe of the plane B D, upon which a weight a weight that is double of W could be ſuſtained by the power P.

For another example; ſuppoſe a fluid, moving with the velocity and direction A C, (*fig.* 3.) ſtrike the plane C E; and ſuppoſe that this plane moves parallel to itſelf in the direction C B, perpendicular to C A, or that it cannot move in any other direction. Then let it be required to find the moſt advantageous poſition of the plane C E, that it may receive the greateſt impulſe from the action of the fluid. Let A P be perpendicular to C E in P, draw A K parallel to C B, and let P K be perpendicular upon it in K, and A K will meaſure the force with which any particle of the fluid impels the plane E C, in the direction C B. For the force of any ſuch particle being repreſented by A C, let this force be reſolved into A Q, parallel to E C, and A P perpendicular to it; and it is manifeſt, that the latter A P only has any effect upon the plane C E. Let this force A P be reſolved into the force A L perpendicular to C B, and the force A K parallel to it; then it is manifeſt, that the former, A L, has no effect in promoting the motion of the plane in the direction C B; ſo that the latter A K, only, meaſures the effort by which the particle promotes the motion of the plane C E in the direction C B. Let E M and E N be perpendicular to C A and C B, in M and N; and the number of particles, moving with directions parallel to A C, incident upon the plane C E, will be as E M. Therefore the effort of the fluid upon C E being as the force of each particle, and the number of particles together, it will be as A K × E M; or, becauſe A K is to A P (= E M) as E N to C E, as $\frac{ME^2 \times EN}{CE}$; ſo that C E being given, the problem is reduced to this, to find when $EM^2 \times EN$ is the greateſt poſſible, or a maximum. But becauſe the ſum of EM^2 and of EN^2 ($= CM^2$) is given, being always equal to CE^2, it follows that $EN^2 \times EM^2$ is greateſt when $EN^2 = \frac{1}{3} CE^2$; in the ſame manner as it was demonſtrated above, that when the ſum of A C and C B (*fig.* 1.) was given, $AC \times CB^2$ was greateſt, when $AC = \frac{1}{3} AB$. But when $EN^2 \times EM^2$ is greateſt, its ſquare root $EN \times EM^2$ is of neceſſity at the ſame time greateſt. Therefore the action of the fluid upon the plane C E, in the direction C B, is greateſt when $EN^2 = \frac{1}{3} CE^2$, and conſequently $EM^2 = \frac{2}{3} CE^2$; that is, when E M, the ſine of the angle A C E, in which the ſtream ſtrikes the plane, is to the radius, as the $\surd 2$ to $\surd 3$; in which caſe it eaſily appears, from the trigonometrical tables, that this angle is of 54° 44′.

Several uſeful problems in mechanics may be reſolved by what was ſhewn in the preceding paragraph. If we repreſent the velocity of the wind by A C, a ſection of the ſail of a windmill, perpendicular to its length by C E, as it follows from the nature of the engine, that its axis ought to be turned directly towards the wind, and the ſail can only move in a direction perpendicular to the axis, it appears, that when the motion begins, the wind will have the greateſt effect to produce this motion, when the angle A C E, in which the wind ſtrikes the ſail, is of 54° 44′. In the ſame manner, if C B repreſent the direction of the motion of a ſhip, or the poſition of her keel, abſtracting from her lee-way, and A C be the direction of the wind, perpendicular to her way, then the moſt advantageous poſition of the ſail C E, to promote her motion in the direction C B, is when the angle A C E, in which the wind ſtrikes the ſail, is of 54° 44′. The beſt poſition of the rudder, where it may have the greateſt effect in turning round the ſhip, is determined in like manner, and the ſame angle enters likewiſe into the determination of the figure of the rhombuſes that form the baſes of the cells in which the bees depoſit their honey in the moſt frugal manner. (See HONEY-*Comb*.) But it is to be carefully obſerved, that when the ſine of the angle A C E is to the radius as $\surd 2$ to $\surd 3$; or, which is the ſame thing, when its tangent is to the radius as the diagonal of a ſquare to its ſide; this is the moſt advantageous angle only at the beginning of the motion of the engine; ſo that the ſails of a common windmill ought to be ſo ſituated, that the wind may indeed ſtrike them in a greater angle than that of 54° 44′. For it is demonſtrable, that when any part of the engine has acquired the velocity c, the effort of the wind upon that part will be greateſt, when the tangent of the angle in which the wind ſtrikes it, is to the radius, not as the $\surd 2$ to 1, but $\surd 2 \times \frac{9c^2}{4a^2} \times \frac{3c}{2a}$ to 1, the velocity of the wind being repreſented by a. If, for example, $c = \frac{1}{3} a$; then the tangent of the angle A C E ought to be double of the radius; that is, the angle A C E ought to be of 63° 26′. If $c = a$; then A C E ought to be of 74° 19′. This obſervation is of the more importance, becauſe, in this engine, the velocity of the parts of the ſail remote from the axis bears a conſiderable proportion to the velocity of the wind, and perhaps ſometimes is equal to it; and becauſe a learned author, Daniel Bernouilli, has drawn an oppoſite concluſion from his computations in his hydrodynamics, by miſtaking a minimum for a maximum; where he infers, that the angle in which the wind ſtrikes the ſail, ought to decreaſe as the diſtance from the axis of motion increaſes; that if $c = a$, the wind ought to ſtrike in an angle of 45°; and that if the ſail be in one plane, it ought to be inclined to the wind, at a medium, in an angle of 50°. How he fell into theſe miſtakes, is ſhewn by Maclaurin, in his Fluxions, § 914.

In like manner, though the angle A C E of 54° 44′ be the moſt advantageous at the beginning of the motion, when a ſhip ſails with a ſide wind; yet it ought to be enlarged afterwards as the motion increaſes. In general, let A a (*fig.* 3.) parallel to C B, be to A C, as the velocity which the engine has already acquired in the direction C B, to that of the ſtream; upon A C produced, take A D to A C as 4 to 3, draw D G parallel to C B, and let a circle deſcribed from the centre C with the radius C a, meet D G in g; and the plane C E ſhall be in the moſt advantageous ſituation for promoting the motion of the engine, when it biſects the angle a C g.

It is generally ſuppoſed, that a direct wind always promotes the motion of a ſhip, the ſail being perpendicular to the wind, more than any ſide-wind; and this has been affirmed in ſeveral late ingenious treatiſes; but, to prevent miſtakes, we are obliged to obſerve, that Maclaurin has demonſtrated the contrary in his Treatiſe of Fluxions, § 919; where other inſtances of this ſecond general problem in mechanics are given, to which we refer. See Maclaurin's Account of ſir Iſaac Newton's Philoſophical Diſcoveries, book ii. chap. 3. p. 173.

Let ϕ denote the abſolute effort of any moving force, when it has no velocity, and ſuppoſe it not capable of any effort when the velocity is W; let F be the effort anſwering to the velocity V, then if the force be uniform, we ſhall have

$$F = \phi \left(1 - \frac{V}{W}\right)$$

For it is the difference between the velocities W and V which is efficient, and the action, being conſtant, will vary as the ſquare of the efficient velocity. Hence we ſhall have this analogy,

$$\varphi : F :: (W - 0)^2 : (W - V)^2,$$

and, conſequently,

$$F = \varphi \left(\frac{W - V}{W}\right)^2 = \varphi \left(1 - \frac{V}{W}\right)^2 \quad \text{Q.E.D.}$$

Although the preſſure of an animal is not actually uniform during the whole time of its action, yet it is nearly ſo, and therefore in general we may adopt this hypotheſis, in order to approximate to the true nature of animal action. On which ſuppoſition the preceding propoſition, as well as the following one, will apply to animal exertion. By retaining the ſame notation, we have alſo

$$W = \frac{V \sqrt{\varphi}}{\sqrt{\varphi} - \sqrt{F}},$$

which formula, applied to the motion of animals, gives the following theorem.

The utmoſt velocity with which an animal, unimpeded, can move, is to the velocity with which it moves when impeded with a given reſiſtance; as the ſquare root of its abſolute force to the difference of the ſquare roots of its abſolute and efficient forces.

Again, to inveſtigate expreſſions by means of which the maximum effect, in machines whoſe motion is uniform, may be determined.

1. It follows from the obſervations made in the preceding part of this article, that when a machine, whether ſimple or compound, is put into motion, the velocities of the impelled and working points are inverſely as the forces which are in equilibrio when applied to thoſe points in the direction of their motion. Conſequently, if f denotes the reſiſtance when reduced to the working point, and v its velocity; while F denotes the force acting at the impelled point, and V its velocity, we ſhall have $F\,V = f\,v$, or introducing t, the time, $F\,V\,t = f\,v\,t$. Hence

In all working machines which have acquired an uniform motion, the performance of the machine is equal to the momentum of the impulſe.

2. Let F be the effort of a force upon the impelled point of a machine, when it moves with a velocity V, the velocity being W, when $F = 0$, and let the relative velocity $W - V = u$.

Then, ſince $F = \varphi \left(\frac{W - V}{W}\right)^2$, by the foregoing propoſition, the momentum of impulſe F V becomes

$$F\,V = V\,\varphi \left(\frac{u}{W}\right)^2 = \varphi \frac{u^2}{W^2} (W - u);$$

becauſe, ſince $W - V = u$, we have $V = W - u$.

Now making this expreſſion for F V a maximum, or ſuppreſſing the conſtant quantities, and making

$$u^2 (W - u) = \text{a maximum},$$

we have, by throwing it into fluxions,

$$2\,u\,\dot{u}\,W - 3\,u^2\,\dot{u} = 0, \text{ or } 2\,W = 3\,u, \text{ or } u = \tfrac{2}{3}\,W:$$

whence, again, $V = W - u = W - \frac{2}{3} W = \frac{1}{3} W$.

Conſequently, when the ratio of V to v is given by the conſtruction of the machine; and the reſiſtance is ſuſceptible of variation, we ought to load the machine more or leſs, till the velocity of the impelled point is one-third of the greateſt velocity of the force, in order that the work done may be a maximum.

Or the work done by an animal is the greateſt when the velocity with which it moves, is one-third of the greateſt velocity with which it is capable of moving when not impeded.

Again, ſince we have

$$F = \varphi \frac{u^2}{W^2} = \varphi \frac{\frac{4}{9} W^2}{W} = \tfrac{4}{9}\varphi,$$

in the caſe of the maximum, we have alſo

$$F\,V = \tfrac{4}{9}\varphi\,V = \tfrac{4}{9}\varphi \cdot \tfrac{1}{3}\,W = \tfrac{4}{27}\varphi\,W,$$

for the momentum of impulſe, or for the work done when the machine is in the beſt ſtate.

Conſequently, when the reſiſtance is a given quantity, we muſt make

$$V : v :: 9f : 4\varphi,$$

which ſtructure of the machine will give the maximum effect $= \frac{4}{27}\varphi\,W$.

If we enquire the greateſt effect on the ſuppoſition that φ only is variable, we muſt make it infinite in the above expreſſion for the work done, which would then become

$$W\,F, \text{ or } W \frac{V}{v} f, \text{ or } W \frac{V}{v} f\,t,$$

including the time in the formula.

Whence we come to this important concluſion, *viz.*

That the ſum of the agents employed to move a machine may be infinite, while the effect is finite.

For the variations of φ, which are proportional to this ſum, do not influence the above expreſſion for the effect. The laſt theorem may be applied to the action of men and of horſes, with more accuracy than might at firſt be ſuppoſed. Obſervations have been made on men and horſes drawing a lighter along a canal, and working ſeveral days together. The force exerted was meaſured by the curvature and weight of the track rope, and afterwards by a ſpring ſteel-yard. The product of the force thus aſcertained into the velocity *per* hour, was conſidered as the momentum; and in this way the action of the men was found to be very nearly as $(W - V)^2$. The action of the horſes, loaded ſo as not to be able to trot, was nearly as $(W - V)^{1\cdot7}$, or as $(W - V)^{\frac{9}{5}}$. Hence the hypotheſis above adopted may, in many caſes, be ſafely aſſumed. According to the beſt obſervations, the force of a man at reſt is on an average about ſeventy pounds, and the utmoſt velocity with which he can walk is about ſix feet *per* ſecond, taken at a medium. Hence in the above theorems $\varphi = 70$, and $W = 6$; conſequently $F = \frac{4}{9}\varphi = 31\frac{1}{9}$lbs., the greateſt force a man can exert when in motion, and he will then move at the rate of $\frac{1}{3}$ W, or two feet *per* ſecond, or rather leſs than 1½ mile *per* hour.

The ſtrength of a horſe is generally reckoned about ſix times that of a man, that is, about 420lbs. at a dead pull. His utmoſt walking velocity is about ten feet *per* ſecond; and therefore his maximum action will be $\frac{4}{9} \times 420 = 186\frac{2}{3}$lbs. and he will then move at the rate of $\frac{1}{3}$ of 10, or $3\frac{1}{3}$ feet *per* ſecond, or nearly 2½ miles *per* hour. In both theſe inſtances we ſuppoſe the force to be exerted in drawing a weight, by a cord running over a pulley, which makes its direction horizontal.

The theorem above given may ſerve to ſhew under what points of view machines ought to be conſidered by thoſe who would labour beneficially for their improvement. The firſt object of utility is in furniſhing the means of giving to the moving force the moſt commodious direction, and when it can be done of cauſing its action to be applied immediately to the body to be moved. Theſe, it is true, can rarely be united, but the former may, in moſt inſtances, be accompliſhed; of which the uſe of the ſimple lever, pulley and wheel and axle, furniſh many examples. The ſecond object gained by the uſe of machines, is an accommodation of the velocity of the work to be performed, to the velocity with which alone a natural power can act. Thus, whenever the working power acts with a certain velocity, which cannot be changed, and the work muſt be performed with a greater velocity, a machine is interpoſed round a fixed ſupport, and the diſtance of the impelled and working points are taken in the proportion of the two given velocities. But the eſſential advantage of machines, and that in fact which properly appertains to the theory of mechanics, conſiſts in augmenting, or rather modifying the energy of the moving power, in ſuch a manner that it may produce effects, of which it would otherwiſe have been incapable. Thus a man might carry up a flight of ſteps twenty pieces of ſtone, each weighing ſay 30lbs. one by one, in as ſmall a time as he could, with the ſame labour, raiſe them all together with a piece of machinery, that would have the velocities of the impelled and working points as twenty to one, and in this caſe the inſtrument would furniſh no real advantage except in ſaving his ſteps. But if a large block of 20 times 30, or 600lbs., were to be raiſed to the ſame height, it would far exceed his utmoſt efforts to accompliſh it, without the intervention of ſome machine. Or the ſame purpoſe may be illuſtrated ſomewhat differently, confining the attention ſtill to thoſe machines whoſe motion is uniform. The product $f\,v$ repreſents, during the unit of time, the effect which reſults from the motion of the reſiſtance; this motion being produced in any manner whatever. If it be produced by applying the moving force immediately to the reſiſtance, it is neceſſary, not only that the product $F\,V = f\,v$, but alſo at the ſame time $F = f$ and $V = v$; if, therefore, as moſt frequently happens, f be greater than F, it will be abſolutely impoſſible to put the reſiſtance in motion, by applying the moving power immediately to it. Now, machines furniſh the means of diſpoſing of the product F V in ſuch a manner, that it may always be equal to $f\,v$, however much the factors F V may differ from the analogous factors in $f\,v$; and conſequently of putting the ſyſtem in motion, whatever may be the exceſs of f above F. Or, generally, as Prony remarks, (Arch. Hydraul. art. 501.) machines enable us to diſpoſe of the factors $F\,V\,t$ in ſuch a manner, that while that product continues the ſame, its factors may have to each other any ratio at pleaſure. Thus, to give another example: ſuppoſe that a man, exerting his ſtrength immediately upon a maſs of 25lbs. can raiſe it vertically, with the velocity of four feet *per* ſecond; the ſame man acting upon a maſs of 1000lbs. cannot give it any vertical motion, though he exerts his utmoſt ſtrength, unleſs he has recourſe to ſome machine. Now he is capable of producing an effect equal to $25 \times 4 \times t$; the letter t being introduced, becauſe, if the labour be continued, the value of t will not be indefinite, but compriſed within aſſignable limits. Thus we have $25 \times 4 \times t = 1000 \times v \times t$; and, conſequently, $v = \frac{1}{10}$th of a foot. This man may, therefore, with a machine as a lever, or axis in *peritrochio*, cauſe a maſs of 1000lbs. to riſe $\frac{1}{10}$th of a foot in the ſame time that he could raiſe 25lbs. 4 feet without a machine; or he may raiſe the greater weight as far as the leſs, by employing forty times as much time. From what has now been ſaid on the extent of the effects which may be attained by machines, it will be ſeen, that ſo long as a moving force exerciſes a determinate effort with a velocity likewiſe determinate, or ſo long as the product of theſe is conſtant, the effects of the machine will remain the ſame: ſo that under this point of view, ſuppoſing the preponderance of the effort of the moving power, and abſtracting from inertia and friction of materials, the convenience of application, &c., all machines are equally perfect. But from what has been ſhewn in the preceding part of this article, a moving force may, by diminiſhing its velocity, augment its effort, and reciprocally. There is, therefore, a certain effort of the moving force, ſuch that its product by the velocity, which comports to that effort, is the greateſt poſſible. Now admitting of the truth of the reſults in the preceding propoſitions $V = \frac{1}{3}\,W$, or $F = \frac{4}{9}\,\varphi$, and theſe two values obtaining together their product, $\frac{4}{27}\,\varphi\,W$ expreſſes the value of the greateſt effect with reſpect to the unit of time; and in practice it will always be adviſable to approach as nearly to theſe values as circumſtances will admit, for it cannot be expected that it can always be exactly attained. But a ſmall variation will not be of much conſequence; for by a well known property of thoſe quantities, which admit of a proper maximum or minimum, a value aſſumed at a moderate diſtance from either of theſe extremes, will produce no ſenſible change in the effect.

If the relation of F to V followed any other law than that which we have aſſumed, we ſhould find from the expreſſion of that law, values of F and V, &c. different from the preceding, but the general method would be ſtill nearly the ſame.

With reſpect to practice, the grand object in all caſes ſhould be to procure an uniform motion, becauſe it is from that which, *ceteris paribus*, the greateſt effect, always reſults. Every irregularity in the motion waſtes ſome of the impelling power, and it is the greateſt only of the varying velocities which is equal to that, which it would acquire if it moved uniformly throughout; for while the motion accelerates, the impelling power is greater than what balances the reſiſtance at that time oppoſed to it, and the velocity is leſs than what the machine would acquire, if moving uniformly; and when the machine attains its greateſt velocity, it attains it becauſe the power is not then acting againſt the whole reſiſtance. In both theſe caſes, therefore, the performance of the machine is leſs than if the power and the reſiſtance were exactly balanced, in which caſe it would move uniformly. Beſides this, when the motion of a machine, and particularly a very ponderous one, is irregular, there are, as we have already remarked in the preceding part of this article, continual repetitions of ſtrains and jolts, which ſoon derange, and ultimately deſtroy the whole ſtructure.

In the preceding remarks and propoſitions, relative to the maximum effect of machines, we have availed ourſelves of an intereſting chapter on this ſubject in Gregory's Mechanics, in which the theory is purſued to a much greater length than our limits will admit of, both with regard to machines whoſe motions are uniform and accelerated; and to which we would refer the reader for further information. See alſo Prony's "Architecture Hydraulique," from art. 487 to 507; and the laſt edition of Ferguſon's Mechanics by Brewſter, in which an intereſting paper on this ſubject is given by profeſſor Leſlie.

Machine for taking down extemporaneous pieces of muſic, commonly called *voluntaries*. Such a contrivance has been long among muſical *deſiderata* of the moſt important kind. To fix ſuch floating ſounds as are generated in the extatic moments of enthuſiaſm, while "bright-eyed fancy

"Scatters from her pictured urn,
Thoughts that breathe, and *notes* that burn,"

would be giving permanence to ideas which reflection can never find, nor memory retain.

The firſt idea of ſuch a contrivance being practicable was ſuggeſted to the Royal Society of London, in a paper written by the late Rev. Mr. Creed, and ſent to the preſident, 1747, under the following title:

"A demonſtration of the poſſibility of making a *machine* that ſhall write *extempore voluntaries*, or other pieces of muſic, as faſt as any maſter ſhall be able to play them, upon an organ, harpſichord, &c. and that in a character more natural and intelligible, and more expreſſive of all the varieties thoſe inſtruments are capable of exhibiting, than the character now in uſe."

This paper was publiſhed the ſame year in the Philoſophical Tranſactions, N° 183, and, afterwards, in Martyn's Abridgment, vol. x. p. 266; and the author's idea always appeared to us ſo feaſible, that we have long wondered at its not having been executed by ſome ingenious Engliſh mechanic.

The firſt mention that we can find to have been made at Berlin, of ſuch a contrivance, was in 1752, in a printed "Weekly Account of the moſt remarkable Diſcoveries in Nature and Science." In 1753, an ample deſcription of ſuch a machine appeared in the ſame weekly publication: and here, in an elaborate preface, the author points out the great want of ſuch a piece of mechaniſm, its utility, and properties; and concludes with ſaying, that this machine, ſo big with advantages to muſic and muſicians, is the *particular invention*, Beſondere Erfindung, of M. Unger.

The deſcription preceded the execution ſome time. The invention was here only recommended to the public, and offered to be completed, and applied to a keyed inſtrument, at a ſmall expence. It was M. Hohlfeld who afterwards conſtructed the machine, and rendered it ſo perfect, that we were aſſured by a great performer, who tried it upon a clavichord, that there was no refinement in muſic which it could not expreſs, except *tempo rubato*.

The deſcription of the Berlin machine ſo much reſembles that propoſed by Mr. Creed, that we ſhall not inſert it here, but refer our readers to the Philoſophical Tranſactions, where he will find that the machine was to conſiſt of two cylinders, which were to be moved by clockwork, at the rate of an inch in a ſecond of time; one of theſe was to furniſh paper, and the other was to receive it when marked by pins or pencils, fixed at the ends of the ſeveral keys of the inſtrument to which the machine was applied. The paper was to be previouſly prepared with red lines, which were to fall under their reſpective pencils.

The chief difficulties in the execution, which have occurred to Engliſh mechanics, with whom we have converſed on the ſubject, were, the preparation of the paper for receiving the marks made by the keys; and the kind of inſtrument which was to ſerve as a pencil, and which, if hard and pointed, would, in the *forte* parts, tear the paper; and if ſoft, would not only be liable to break when uſed with violence, but would be worn unequally, and want frequent cutting.

In the Berlin machine the pencils were approximated according to Mr. Creed's idea, and made to terminate in a very narrow compaſs, ſo that paper of an uncommon ſize was not requiſite; but it was not found neceſſary to prepare the paper, as propoſed in the Philoſophical Tranſactions; for the degree of gravity or acuteneſs of each ſound was aſcertained by a ruler applied to the marked paper, when taken off the cylinder.

About the year 1780, the late ingenious and marvellous mechanic Merlin, ſtimulated by the reports of this machine having been ſucceſsfully conſtructed in Germany, and by our earneſt recommendation of the undertaking, went to work, and apparently vanquiſhed all the difficulties of conſtruction, except the time inevitably neceſſary for its completion; as he was never able to ſimplify the mechaniſm ſo much as to render its appropriation within the reach of great compoſers and voluntary players in general, to whoſe uſe only it ſeems to belong; he diſpoſed of his model to a foreign nobleman, who had it conveyed to Germany, and we believe never fabricated another machine of the ſame kind. See MERLIN.

MACHINE, in *Dramatic Poetry*, is when the poet brings ſome divinity or ſupernatural being upon the ſtage; to perform ſome exploit, or ſolve ſome difficulty, out of the reach of human power.

The machines of the drama are gods, angels, ghoſts, &c. They are ſo called from the machines or contrivances by which they are repreſented upon the ſtage, and afterwards removed again.

Hence the uſe of the word machine has alſo paſſed into the epic poem; though the reaſon of its name be there wanting. It denotes, in both caſes, the intervention or miniſtry of ſome divinity; but as the occaſion of machines in the one and the other is ſomewhat different, the rules and laws of managing them are different likewiſe.

The ancient dramatic poets never brought any machine on the ſtage, but where there was an abſolute neceſſity for the preſence of a god; and they were generally laughed at for ſuffering themſelves to be reduced to ſuch a neceſſity. Accordingly, Ariſtotle lays it down as an expreſs law, that the unravelling of the piece ſhould ariſe from the fable itſelf, and not from any foreign machine, as in the Medea. Horace is ſomewhat leſs ſevere, and contents himſelf with ſaying, that the gods ſhould never appear, unleſs where the *nodus*, or knot, is worthy of their preſence; "Nec deus interſit, niſi dignus vindice nodus—inciderit." But it is quite otherwiſe with the epopea; in that there muſt be machines every where, and in every part. Homer and Virgil do nothing without them. Petronius, with his uſual fire, maintains, that the poet ſhould deal more with the gods than with men; that he ſhould every where leave marks of his prophetic raptures, and of the divine fury that poſſeſſes him; that his thoughts ſhould be all full of fables, that is, of allegories and figures: in fine, he will have a poem diſtinguiſhed from a hiſtory in all its parts; not ſo much by the verſes, as by that poetical fury, which expreſſes itſelf wholly by allegories; and does nothing but by machines, or the miniſtry of the gods. A poet, therefore, muſt leave it to the hiſtorian to ſay, that a fleet was diſperſed by a ſtorm, and driven to foreign ſhores; and muſt himſelf ſay, with Virgil, that Juno went to ſeek Æolus: and that this god, at her requeſt, turned the winds looſe againſt the Trojans: he muſt leave the hiſtorian to write, that a young prince behaved with a great deal of prudence and diſcretion on all occaſions; and muſt ſay, with Homer, that Minerva led him by the hand in all his enterprizes: let an hiſtorian ſay, that Agamemnon, quarrelling with Achilles, hath a mind to ſhew him, though miſtakenly, that he can take Troy without his aſſiſtance; the poet muſt ſay, that Thetis, piqued at the affront her ſon had received, flies up to heaven, there to demand vengeance of Jupiter: and that this god, to ſatisfy her, ſends the god Somnus, or Sleep, to Agamemnon, to deceive him, and make him believe that he ſhall take Troy that day.

It is thus that the epic poets uſed machines in all parts of their works; in the Iliad, Odyſſey, and Æneid, the propoſition mentions them; the invocation is addreſſed to them; and the narration is full of them: they are the cauſes of actions; they make the knots, and at laſt they unravel them. This laſt circumſtance is what Ariſtotle forbids in the drama; but it is what Homer and Virgil have both practiſed in the epopea. Thus Minerva fights for Ulyſſes againſt Penelope's lovers; helps him to deſtroy them; and, the next day, herſelf makes the peace between Ulyſſes and the Ithacans; which cloſes the Odyſſey. The uſe of machines in the epic poem is, on ſome accounts, entirely oppoſite to what Horace preſcribes for the theatre. In tragedy, that critic will never have them uſed without an abſolute neceſſity; whereas, in the epopea, they ſhould never be uſed, but where they may be as well let alone; and where the action appears as if it did not neceſſarily require them. How many gods and machines does Virgil implore to raiſe the ſtorm that drives Æneas into Carthage; which yet might eaſily have happened in the ordinary courſe of nature.

In Milton's Paradiſe Loſt, moſt of the actors are ſupernatural perſonages; and in Voltaire's Henriade, the poet has made excellent uſe of St. Louis.

Machines, in the epic poem, therefore, are not contrivances of the poet, to recover himſelf after he has made a falſe ſtep, nor to ſolve any difficulty peculiar to ſome part of the poem; but it is the preſence of a divinity, and ſome ſupernatural and extraordinary action, which the poet inſerts in moſt of the incidents of his work, to render it more majeſtic and admirable, and to train up his readers to piety and virtue. This mixture ſhould always be ſo managed, as that the machines may be retrenched, without retrenching any thing from the action. As to the manner in which the machines are to act; it may be obſerved, that in the old mythology, there are gods both good, bad, and indifferent; and that our paſſions may be converted into ſo many allegorical divinities: ſo that every thing, both good and bad in a poem, may be attributed to theſe machines, and may be tranſacted by them. They do not, however, always act in the ſame manner; ſometimes they act without appearing, and by ſimple inſpirations, which have nothing in them extraordinary or miraculous; as when we ſay, the devil ſuggeſted ſuch a thought, &c. The ſecond manner of acting is entirely miraculous; as when a divinity preſents itſelf viſible before men, ſo as to be known by them; or when they diſguiſe themſelves under ſome human form without diſcovering themſelves. The third manner partakes of each of the two, and conſiſts in oracles, dreams, and extraordinary inſpirations: all which Boſſu calls *demi-machines*.

All theſe manners ought to be ſo managed as to carry a veriſimilitude: and though veriſimilitude be of a vaſt extent in machines, as being founded on the divine power, yet it has its bounds. See farther, on the importance and uſe of machinery, the article Epic *Poem*.

Machine, in *Agriculture*, a term applied to inſtruments of various kinds which are contrived either for the purpoſe of leſſening labour or performing the different operations and proceſſes of the art with greater accuracy and correctneſs, ſuch as thoſe of ſowing, drilling, reaping, threſhing, winnowing, and a great many others. The term is moſt commonly employed when the nature of the tool is of the more complex kind. It may, however, be employed with propriety in many other circumſtances. See Threshing *Machine*.

Machine, *Architectonical*, is an aſſemblage of pieces of wood ſo diſpoſed, as that, by means of ropes and pullies, a ſmall number of men may raiſe vaſt loads, and lay them in their places. Such are cranes, &c.

It is hard to conceive what ſort of machines the ancients muſt have uſed to raiſe thoſe immenſe ſtones found in ſome of the antique buildings. See Machine, *ſupra*.

Machine, *Blowing*. See Bellows, and Blowing *Machine*.

Machine, *Bruiſing*, a contrivance for the purpoſe of cruſhing and reducing grain, pulſe, malt, and other articles, ſome of which are employed as team food. Machines of this kind are made in London by Rowntree and others.

Machine, *Chaff-cutting*, a tool contrived for the purpoſe of cutting ſtraw, hay, and other ſimilar materials into chaff for the purpoſe of food for team-horſes, and other animals. There are various deſcriptions of this kind of machinery which act on very different principles, and ſome of them have lately undergone very much improvement. See Chaff-cutter.

Machine, *Draught*, a ſimple contrivance formed for the purpoſe of aſcertaining the force or power of draught, in drawing ploughs, and various other implements where draught is required. A machine of this ſort, invented by Mr. More, late ſecretary to the Society for the Encouragement of Arts, &c. in London, is thus deſcribed by Mr. Young in the firſt volume of the Annals of Agriculture. It is a ſpring coiled within a cylindrical caſe, having a dial-plate, marked with numbers like that of a clock, and ſo contrived that a hand moves with the motion of the ſpring, and points to the numbers in proportion as the force is exerted: for inſtance, when the draught equals 1 cwt. over a pulley, the hand points to *fig.* 1; when the draught is equal to 2 cwt. it points to *fig.* 2; and ſo on. Till this very uſeful machine was invented, Mr. Young ſays, it was exceedingly difficult to compare the draught of different ploughs, as there was no rule to judge but by the exertions of the horſes as apparent to the eye; a very indeciſive mode of aſcertaining their force.

Machine, *Drill*, that ſort of tool which is employed in ſowing and depoſiting various kinds of grain, pulſe, and ſmall ſeeds, in drills or rows. They are very differently formed, according to the purpoſes for which they are intended, and the manner of drilling which is intended to be practiſed.

They require to be conſtructed with great correctneſs, and in as ſimple a manner as poſſible, in order that they may perform their work with accuracy, both in reſpect to the drills, the quantity of ſeed, and the depth of depoſiting it in the ſoil.

In the choice of this ſort of machinery, the farmer ſhould be principally directed by the nature and extent of his land, the ſituation which it poſſeſſes, and the kinds of crops which he intends to cultivate. They have lately been ſo contrived, as, by ſlight alterations in the ſowing parts, to be capable of not only ſowing grain as well as ſmall ſeeds, but of executing the work at different diſtances, and in a greater or leſs number of rows at once, as circumſtances may require.

There are ſeveral machines of this nature, which perform the buſineſs in a very exact and regular manner; among which are Cook's, Bailey's, Amoſe's, M'Dougal's, and many others; each of which ſow ſeveral rows at the ſame time, and ſome of them are likewiſe capable of forming horſe-hoes.

Beſides theſe, there are alſo drills conſtructed for particular ſorts of crops, as thoſe of peas, beans, turnips, &c. See PLOUGH *Drill*, and TURNIP *Drill*.

A drill machine, invented by Mr. Robert Salmon of Woburn, Bedfordſhire, which obtained the premium given by the duke of Bedford, at Woburn ſheep-ſhearing, a few years ago, for the beſt newly-invented agricultural implement, is deſcribed below. This machine drills and ſows at the ſame time; and the principal improvement in it, as in Cook's drill, and others, conſiſts in conſtructing it in ſuch a manner, that the workman who holds the drill has a perfect command upon it, with reſpect to the direction in which it ſhall move, even though the horſe which draws it ſhould deviate from the line the drill is intended to follow. In *Plate* (*Machines*) *Agriculture*, is given a deſcriptive repreſentation of the machine, in which *fig.* 1 is a ſection of a part, *fig.* 2 an elevation of the ſame, *fig.* 4 is a perſpective view of the whole, and *figs.* 3 and 5 detached parts.

The great wheels, A, A, *fig.* 4, have their axle-trees attached to the bed B, to which are framed the long handles, D, D, forming a frame independent of the remainder of the machine, and having no connection with it, except in the middle of the bed B, where a ſhort beam, E, is jointed to it, as is well explained in *fig.* 1; the other end of this beam is mortiſed into a croſs beam F, to which the three drills, G, G, G, are fixed; a frame formed of two horizontal pieces, H, H, *figs.* 2 and 4, and four vertical pieces, I, I, I, I, is erected upon F; the handles, D, D, paſs between H, H, but are not fixed thereto; the hook *a*, by which the machine is drawn, is fixed to the two middle uprights, I, I, and a ſtrong chain leads to the harneſs of the horſe employed; K is the ſeed-box ſupported from H, H, by two uprights for the purpoſe; the box is a fruſtum of a pyramid, and joins at the bottom to a priſmatic box, containing the ſeed-roller *b*, *fig.* 1, which is exactly the ſame length as the box, and comes through its ends, its pivots being ſupported by a piece of iron-plate fixed at the end of the box, as ſeen in *fig.* 4; a bruſh, *d*, preſſes upon the roller, and is adjuſtable by a ſcrew that it may always bear upon it with an equal degree of force; a number of notches is cut in the circumference of the roller, and as the box K is full of ſeed, it always reſts upon the roller; when it turns round, it takes one of the notches full of ſeed, and paſſing it by that means under the end of the bruſh *d*, delivers it into a tin-plate tube *r*, which conveys it down into the furrow made by the drill; the roller has three ſeries of notches anſwering to the three drills G, G, G; at *e*, a piece of leather preſſes againſt the roller, to prevent any ſeed getting down, except that which paſſes under the bruſh *d*; *f* is a ſlider, which ſtops the ſeed from coming down to the roller, when ſhoved in, and is uſed when the machine is required to advance without ſowing, or when a leſſer number of rows is required to be ſown. The roller is turned by means of an endleſs chain, *q q*, paſſing round a groove made in the middle of the roller, from thence it proceeds through a block of pullies at *t*, ſhewn ſeparate in *fig.* 5, to a ſmall wheel *h*; the block, *t*, is made of caſt-iron, and ſlides freely up and down between the two innermoſt uprights, I, I, of the frame; its weight keeps the chain always tight, and prevents it from ſlipping without turning the roller; the wheel, *h*, is fixed upon an axle *p*, on the end of which is a cog-wheel, turned by another cog-wheel on the nave of the great wheel A; theſe wheels are encloſed in a box *k*, which likewiſe contains a contrivance for diſengaging the wheels, ſhewn on a larger ſcale in *fig.* 3, where *p* is a ſection of the axle *p*, paſſing through a long ſtaple fixed to the bed B; it can ſlide up and down in this ſtaple, except when confined by a catch *o*, preſſed againſt it by a ſpring. In the preſent poſition, the cog-wheels are engaged to work together: but by pulling the cords *m* and *l*, the former draws back the catch *o*; and the other, by means of the crooked lever *n n*, raiſes up the axle *p*, and diſengages the cog-wheels; the return of the catch, *o*, prevents its deſcent; the cords, *l* and *m*, are conducted to the end of the handles, D, D where they are both attached to one handle, in reach of the workman who guides the machine.

The operation of the drill is exceedingly ſimple. As the horſe draws it along by means of the chain, the drills, G, G, G, make the furrows, and the ſeed-roller delivers the ſeed in ſmall quantities, and at regular intervals into them. As the hook *a*, from which the chain draws, is placed nearly in the centre of the machine, it will eaſily be made to follow any other line than that in which the horſe draws, by turning the handles, D, D, to one or other ſide. This alters the direction of the wheels, A, A, which immediately proceed in that line, and the drill follows them. This quality is of the greateſt conſequence in making ſtraight work. L is a croſs piece fixed to the handles, D, D, and ſupporting a handle M, by which, and one of D, the workman holds when he guides the drill, as he is then in a poſition to ſee the drills made laſt, and adapt the preſent ones to them; the wheel always going in the laſt made drill. Another handle, ſimilar to M, is fixed to the other end of L, to be uſed when the machine is on the other ſide of the work done laſt. The drills are fixed to the piece F by ſcrews, and their diſtance from one another can be altered at pleaſure. The ſeed-box containing the roller is made in two halves, connected by hooks, ſo that it can be taken apart, and the roller removed for a freſh one to be put in with different ſized notches, for ſowing a different kind of grain.

The drawing was taken from a machine made by Mr. Shepherd, Woburn, and exhibited at Woburn ſheep-ſhearing, June 1808. Mr. Salmon has made a great number of the ſame pattern, which are now in uſe, and are found to anſwer well. Several of them have five drills inſtead of three, and are in that caſe worked by one horſe.

In this drill, at whatever diſtance the ſhares are placed to go from each other, the diſtance from the wheels to the two outſide rows is alway equal thereto; conſequently, when at work, one or the other of the wheels always runs in the laſt made drill, thereby guaging accurately the interval between each bout the drill goes; and as the holder always goes in the line of the wheel, he can diſtinctly ſee and correct the ſmalleſt error that may have been made in any previous bout.

In all caſes, one horſe is ſufficient to draw this drill either for three or more rows, as little depends on the horſe's inclination; and a driver can be diſpenſed with, where tractable horſes are uſed. As in all machines of this ſort, in proportion to the number and diſtance of rows made, ſo will be the quantity of work performed.

MACHINE, *Electrical.* See ELECTRICAL *Machine*.

MACHINE, *Fan*, in *Agriculture*, a common name applied to that ſort of tool which is employed in removing the chaff from the grain. See WINNOWING *Machine*.

MACHINE, *Land-Levelling*, the name of an uſeful machine, invented by Mr. David Charles, for the purpoſe of rendering high ridges and other inequalities, in ſuch lands as are in a ſtate more level and even in their ſurfaces. It would ſeem probable that no effective implement of this ſort has hitherto been introduced. But ſuch a machine is ſaid, in "Tranſactions of the Society of Arts," to be uſeful and neceſſary even in the moſt fertile parts of the country, where the improved ſyſtem of drill-huſbandry has been introduced, or even where there is any attention to the waſte of time, or to the eaſe of cattle in the act of ploughing; in order to get rid of crooked or unequal ridges, without either a ſummer fallow by croſs ploughing, or elſe by frequent repetitions of ploughing in the winter and ſpring, which the humidity of this climate will not allow in every kind of ſoil. "Fourteen acres of land were reduced with this tool by the inventor to a perfect level, where the crowns of the ridges were about two feet higher than the furrows, and where they were crooked and of unequal breadths. But the chief ſucceſs has been upon a field of eight acres, which lay in an unprofitable ſtate, and which is a deep clay, that had produced a crop of wheat from an old lay ſod the former year, without any manure, which was winter ploughed, and lay in that ſtate until the machine was introduced the firſt dry weather in April. It was preceded by two horſe ploughs, taking perhaps a ſquare of an acre at once: theſe looſened the ſoil the depth of a common furrow, and twice the breadth acroſs the ridges. The levelling machine followed, drawn by two oxen and two horſes, with a man at each handle, to preſs it down where the height was to be removed, and to lift up the body by the handles where it was to be diſcharged. Thus, four men, one driver, and eight head of cattle, will more effectually level from half an acre to three roods in one day, according as the earth is light or heavy, than ſixty or eighty men would accompliſh with harrows and ſhovels, &c. even with the aſſiſtance of a plough. In ſandy ground, where the depth of one furrow will bring all to a level, as much, of courſe, will be done in one day as two ploughs can cover;" but in this caſe, the ground required to be gone over ſeveral times. It is further ſtated, that "after this field was levelled, the backs of the ridges, as they are termed, which were ſtripped of their vegetable mould, were ploughed up, the furrows not requiring it. They were alſo harrowed, and the field copiouſly manured with lime-compoſt, harrowed in, and broke into nine feet ridges, perfectly ſtraight, in order to introduce Duckit's drill. It was ſown under furrow, broad-caſt, the laſt of it not until the 13th of May, and was cut down a reaſonable crop the 4th of September." And "the field now lies in proper form, well manured, with the advantage of a fair crop from heavy tenacious ground, without loſing a ſeaſon, and in a year by no means favourable." The writer is "well aware there are many ſhallow ſoils, where it may be hazardous to remove the enriched ſurface, and truſt perhaps one half of the land for a crop that had never before been expoſed to the atmoſphere; but where the ſoil is ſufficiently deep, or there is a good under-ſtratum, with manure at hand to correct what is ſour for want of expoſure and tillage, it is evident, from this experiment, that no riſk is run." And in order "to avoid the expence of a fallow, and to lay out ground in ſtraight and even ridges, even where drill huſbandry is not practiſed, ſhould be objects to every rational farmer: but where the new ſyſtem is intended to be adopted, it becomes indiſpenſibly neceſſary. In laying down lawns, parks, &c. where furrows are an eye-ſore, or places inacceſſible to wheel-carriages from their declivity, and from which earth is to be removed, it will alſo be found equally uſeful." Beſides theſe, there are many other caſes in which the old rounded ridges may be levelled down with great advantage, either by this or ſome other means.

A repreſentation of this machine is given at *fig.* 1. in *Plate* (*Machines*) *Agriculture*, in which *a*, *fig.* 2. is a part of the pole, to which the oxen or horſes which draw the machine are faſtened, and which is attached to the machine by a pin at *b*; *c*, *c*, the two wheels, ſhod with iron, which run upon the axle *d*; *e e*, the upper frame work of the machine, extending from the axle to the extremity of the handles, *f*, *f*, and ſecured firmly by the croſs pieces, *g*, *g*, the curved iron ſliders of the machine, which may be raiſed or depreſſed a little by means of the pins, *h*, *h*, which paſs through holes in the wood-work, and alſo in the iron ſliders. Theſe ſliders form one piece with the back iron ſcraper *i*, in the manner more fully explained in *fig.* 3, *k*, the wooden back of the machine, which ſhould be made ſtrong, to reſiſt the weight of the earth when collected therein. The iron ſcraper ſhould be firmly ſecured to this by ſcrews and iron work; *l*, *l*, the wooden ſides of the machine, firmly connected with the back and frame work, in order to aſſiſt in collecting the earth to be removed; *m*, a ſtrong croſs piece, into which the ribs which ſupport the back are well mortiſed.

The interior part of the back of the machine is ſhewn at *k*, in *fig. 3*: *i*, the iron ſcraper, ſharp at the bottom, firmly ſcrewed to the back of the machine; *g*, *g*, parts of the ſide irons or ſliders, ſhewing the mode in which they are united with the ſcraper *i*; *m*, the croſs piece already deſcribed.

MACHINES, *Military*, among the *Ancients*, were of three kinds: the firſt ſerving to launch arrows, as the ſcorpion; or javelins, as the catapulta; or ſtones, as the baliſta; or fiery darts, as the pyrabolus: the ſecond ſerving to beat down walls, as the battering ram and terebra: and the third to ſhelter thoſe who approach the enemies wall, as the tortoiſe or teſtudo, the vinea, pluteus, and the towers of wood. Theſe machines, together with their proportions and properties, are deſcribed in the works of Vitruvius, Ammianus Marcellinus, and other writers. Mr. Groſe has given deſcriptions and drawings of theſe in the *firſt* volume of his "Military Antiquities," chap. xii.

MACHINE, *Stone-lifting*, in *Agriculture*, an implement of the triangle kind, ſimilar to that uſed by wood-cutters for weighing bark, conſtructed for the purpoſe of raiſing large ſtones of ſome tons weight uſed in the northern parts of Scotland, and many other places. It is ſuppoſed to ſave much expence in powder and boring as well as labour, three men being ſufficient to work it. It is deſcribed in the Agricultural Survey of Perthſhire in this manner.

"The three legs, *a d*, *b d*, and *c d*, which are ſhewn at *fig.* 4, are beams of any hard wood, four inches thick, ſix inches broad, and about fourteen feet long. Their thinneſt ſide points inwards, which gives them more ſtrength. Their feet form on the ground an equilateral triangle *a b c*, and their three tops at *d* are fixed together by an iron rod, which paſſes through each. The two legs *a d* and *b d* are fixed to one another by the windlaſs *k*, and by the croſs-bar *o p q*. There are two pullies *e* and *f*, with an iron hook two inches in circumference to each; *g g g* may be (more than one, but rather) one iron chain which goes round the ſtone *n*, while lying in the ground at *m*, below its greateſt diameter, or where it begins to become narrow. This chain conſiſts of rounded links, which are about three inches long, and about the thickneſs of a man's little finger. It has a hook at one end, that may be put into any link towards the other end, which will make it embrace the ſtone exactly, and be of the ſame circumference, where the ſtone touches the earth; *h g*, *h g*, *h g*, are ſhorter chains of the ſame workmanſhip, whoſe hooks are fixed into links of the ſurrounding chain at *g g g*, and ſo on round the ſtone, having the correſponding link of each fixed on the hook of the lower pulley at *h*. The whole rope muſt be of the ſame thickneſs with the two great hooks, two inches in circumference.

"All things being thus prepared, two men turn round the handles of the cylinder, and the waggoner aſſiſting them by applying a lever to any ſide of the ſtone that ſeems to be firmeſt, they force it aloft, and hold it up at the proper height, until the driver put his carriage backward between *b* and *c*, which carriage ought to have a ſtrong frame upon four low ſtout wheels; then the ſtone is let gently down and carried away."

By this ſort of machine large ſtones or other bodies can be raiſed and removed without any great difficulty.

Machine, *Threſhing*, a contrivance made uſe of inſtead of the flail for threſhing corn and other ſeed crops. See Threshing *Machine*.

Machine, *Water*, or *Hydraulic*, is either uſed to ſignify a ſimple machine, ſerving to conduct or raiſe water; as a ſluice, pump, &c. or ſeveral of theſe acting together, to produce ſome extraordinary effect; as the

Machine *of Marli*. See Marli. See alſo Fire-*engine*, Steam-*engine*, and Water-*works*.

Machine, *Water-raiſing*, a ſort of machine contrived for the purpoſe of raiſing water a few feet high by the power of the *wind*, for the purpoſe of draining moraſſes, or of watering lands on a higher level, and other ſimilar uſes. A ſection of it is given at *fig.* 5, and it is deſcribed by the author of the Philoſophy of Agriculture and Gardening to "conſiſt of a windmill ſail placed horizontally, like that of a ſmoke-jack, ſurrounded by an octagon tower; the diverging rays of this tower, *a b*, *a b*, may conſiſt of two-inch deals only, if on a ſmall ſcale, or of brick-work if on a larger one. Theſe upright pillars are connected together by oblique horizontal boards at A B, by which boards placed horizontally from pillar to pillar in reſpect to their length, but at an angle of about 45 degrees in reſpect to their breadth, ſo as to form a complete octagon, including the horizontal windmill ſail near the top of it; the wind, as it ſtrikes againſt any of them, from whatever quarter it comes, is bent upwards, and then ſtrikes againſt the horizontal wind-ſail. Theſe horizontal boards, which form the ſides of the octagon, may either be fixed in their ſituations, or be made to turn upon an axis a little below their centres of gravity, ſo as to cloſe themſelves on that ſide of the octagon tower moſt diſtant from the wind. It may be ſuppoſed that the wind thus reflected, would loſe conſiderably of its power before it ſtrikes on the wind-ſail; on fixing a model of ſuch a machine, however, on the arm of a long whirling lever, with proper machinery to count the revolutions of the wind-ſail, when thus included in a tower, and moving horizontally; and then when moved vertically, as it was whirled on the arm of the lever with the ſame velocity, it was found on many trials by Mr. Edgeworth, in Ireland, and Dr. Darwin, at Derby, that the wind, by being thus reverted upwards by a fixed planed board, did not ſeem to loſe any of its power. And as the height of the tower may be made twice as great as the diameter of the ſail, there is reaſon to conclude, the doctor thinks, that the power of the horizontal wind-ſail may be conſiderably greater, than if the ſail was placed nearly vertically oppoſed to the wind in the uſual manner. At the bottom of the ſhaft of the wind-ſail is placed a centrifugal pump with two arms at D, C, which conſiſts ſimply of an upright bored trunk, or cylinder of lead, with two oppoſite arms with an adapted valve at the bottom to prevent the return of the water, and a valve at the extremity of each arm to prevent any ingreſs of air above the current of the water as it flows out; *c c c c* is a circular trough to receive the ſtreams of water from C and D, to convey them where required in any particular operation or proceſs.

And at *fig.* 6 is another machine, invented by Mr. Sergeant, of Whitehaven, calculated for raiſing or forcing water in particular caſes, as for domeſtic or other uſes. It is extremely ſimple and cheap in its conſtruction, the whole, excluſive of the pump pipes, &c. not coſting more than five pounds. The object for which it was particularly contrived was that of raiſing water for the ſupply of a gentleman's houſe from a ſtream running at the diſtance of about 140 yards. In which intention a dam was made a little diſtance above, ſo as to cauſe a fall of about four feet, the water being brought by a wooden trough, into which was inſerted a piece of two-inch leaden pipe, a part of which is ſeen at *a*, in the figure; the ſtream of this pipe is ſo directed as to run into the bucket *b c*, when the bucket is elevated; but as ſoon as it begins to deſcend, the ſtream flows over it, and goes to ſupply the wooden trough, or well, in which the foot of the forcing pump, *c*, ſtands, of three inches bore; *d* is an iron cylinder attached to the pump rod, which paſſes through it, which is filled with lead, and is in weight about 240 pounds. This is the power which works the pump, forcing the water through 240 feet of inch pipe from the pump up to the houſe. At *e* a cord is fixed, which, when the bucket comes to within four or five inches of its loweſt projection, becomes ſtretched, and opens a valve at the bottom of it, through which the water diſcharges itſelf. This ſort of pump may be found very beneficial in a variety of inſtances where its application can be admitted.

Machine, *Wind*. See Anemometer, and Wind *Machine*.

MACHINERY, in the Lyric theatre, or Opera-houſe. In the early operas of Italy, during the 17th century, it ſeldom happened that the names of the poets, compoſers, or ſingers, were recorded in printed copies of the words; though that of the machiniſt was ſeldom omitted; and much greater care ſeems to have been taken to amuſe the eye than the ear or intellect of thoſe who attended theſe ſpectacles.

In 1675, we are told, in the Theatrical Annals of Venice, that a muſical drama, called La Diviſione del Mondo, written by Giulio Ceſare Corradi, and ſet by Legrenzi, excited univerſal admiration, by the ſtupendous machinery and decorations with which it was exhibited. And in 1680, the opera of Berenice, ſet by Domenico Freſchi, was performed at Padua in a manner ſo ſplendid, that ſome of the decorations recorded in the printed copy of the piece ſeem worthy of notice in this article. The muſical drama conſiſted of poetry, muſic, dancing, machinery, and decorations; and it would be curious to point out the encroachments which any one of theſe conſtituent parts at different periods has made upon the reſt. In the beginning it was certainly the intention of opera legiſlators to favour Poetry, and make her miſtreſs of the feaſt; and it was a long while before Muſic abſolutely took the lead. Dancing only ſtept into importance during the laſt century; but very early in the 17th century, machinery and decorations were ſo important, that little thought or expence was beſtowed on poetry, muſic, or dancing, provided ſome means could be deviſed of exciting aſtoniſhment in the ſpectators, by ſplendid ſcenes and ingenious mechanical contrivances.

In the opera of Berenice juſt mentioned, there were choruſes of one hundred virgins, one hundred ſoldiers, one hundred horſemen in iron armour, forty cornets of horſe, ſix trumpeters on horſeback, ſix drummers, ſix enſigns, ſix ſacbuts, ſix great flutes, ſix minſtrels playing on Turkiſh inſtruments, ſix others on octave flutes, ſix pages, three ſerjeants, ſix cymbaliſts, twelve huntſmen, twelve grooms, ſix coachmen for the triumph, ſix others for the proceſſion, two lions led by two Turks, two elephants by two others, Berenice's triumphal car drawn by four horſes, ſix other cars with priſoners and ſpoils drawn by twelve horſes, ſix coaches for the proceſſion. Among the ſcenes and repreſentations in the firſt act, was a vaſt plain, with two triumphal arches; another, with pavilions and tents; a ſquare prepared for the entrance of the triumph; and a foreſt for the chace. Act II. the royal apartments of Berenice's temple of vengeance; a ſpacious court, with a view of the priſon; and a covered way for the coaches to move in proceſſion. Act III. the royal dreſſing room, completely furniſhed; ſtables with one hundred live horſes; portico adorned with tapeſtry; a delicious palace in perſpective. And beſides all theſe attendants and decorations, at the end of the firſt act, there were repreſentations of every ſpecies of chace: as of the wild boar, the ſtag, deer, and bears; and at the end of the third act, an enormous globe deſcends from the ſky, which opening divides itſelf into other globes that are ſuſpended in the air, upon one of which is the figure of Time, on a ſecond that of Fame, on others, Honour, Nobility, Virtue, and Glory. Had the ſalaries of ſingers been at this time equal to the preſent, the ſupport of ſuch expenſive and puerile toys, would have inclined the managers to enquire, not after the beſt, but the cheapeſt vocal performers they could find; as ſplendid ballets often oblige them to do now; and it is certain, that during the 17th century, the diſtinctive characteriſtic charm of an opera was not the muſic, but machinery. The French eſtabliſhed muſical dramas in their court and capital during the rage for mythological repreſentations, to which they have conſtantly adhered ever ſince; and when they are obliged to allow the muſical compoſition and ſinging to be inferior to that of Italy, they comfort themſelves and humble their adverſaries by obſerving, that their opera is, at leaſt, a fine thing to ſee: "c'eſt au moins un beau ſpectacle, qu'un opera en France."

Machinery, in *Mechanics*, may be conſidered as the operative and moving parts of machines; it is, however, very generally, though perhaps improperly, applied to include all the parts of machines, fixed as well as moving, and in this view may be conſidered as the inſtruments or parts by which the principles of mechanics are carried into execution, and rendered applicable to all the purpoſes of arts and manufactures.

The denomination machine is now vulgarly given to a great variety of ſubjects that have very little analogy by which they can be claſſed with propriety under one name: we ſay a travelling machine, a bathing machine, a copying machine, a threſhing machine, an electrical machine, &c. &c. The only circumſtances in which all theſe agree, ſeem to be, that their conſtruction is more complex and artificial than the utenſils, tools, or inſtruments which offer themſelves to the firſt thoughts of uncultivated people; they are more artificial than the common cart, the bathing tub, the flail, or the glaſs tube which firſt diſcovered the phenomena of electricity. In the language of ancient Athens and Rome, the term was applied to every tool by which hard labour of any kind was performed; but in the language of modern Europe, it ſeems reſtricted either to ſuch tools or inſtruments as are employed for executing ſome philoſophical purpoſe, or of which the conſtruction employs the ſimple mechanical powers in a conſpicuous manner, ſo that their operation and energy engage the attention. It is nearly ſynonimous, in our language, with *engine;* a term altogether modern, and in ſome meaſure honourable, being beſtowed only, or chiefly, on contrivances for executing work in which ingenuity and mechanical ſkill are manifeſt. Either of theſe terms, machine or engine, is applied with impropriety to contrivances in which ſome piece of work is not executing on materials, which are then ſaid to be manufactured. A *travelling* or *bathing* machine is ſurely a vulgariſm.

A machine or engine is, therefore, a tool, but of complicated conſtruction, peculiarly fitted for expediting labour, or for performing it according to certain invariable principles: and we ſhould add, that the dependence of its efficacy or mechanical principles muſt be apparent, and even conſpicuous.

The contrivance and erection of ſuch works conſtitute the profeſſion of the engineer; a profeſſion which ought by no means to be confounded with that of the mechanic, the artiſan, or manufacturer. It is one of the *Artes liberales;* as deſerving of the title as medicine, ſurgery, architecture, painting, or ſculpture. Nay, whether we conſider the importance of it to this flouriſhing nation, or the ſcience that is neceſſary for giving eminence to the profeſſor, it is very doubtful whether it ſhould not take place of the three laſt named, and go *pari paſſu* with ſurgery and medicine.

In the language of our practical mechanics, the terms *machine*, *engine*, and *mill*, are uſed without a proper diſtinction of the claſſes of machinery to which they ſhould in ſtrictneſs be applied. All theſe denominations are alike the practical applications of the ſcience of mechanics, and conſiſt only of different combinations of the mechanical powers. Though the combinations and modifications which the ingenuity of mankind is conſtantly producing are endleſs, ſtill it is poſſible, by a proper claſſification, to arrange them under their proper terms, to avoid the confuſion which at preſent prevails amongſt thoſe of our ingenious countrymen, who have laboured to improve the arts dependent on mechanics, without troubling themſelves to fix upon the moſt preciſe language in which to expreſs their ideas. If we might preſume to decide upon a proper definition of theſe words, which has not hitherto been done, we ſhould adviſe that the term machine be uſed as generic, and applied to any mill, engine, inſtrument, or apparatus having moving parts. That machinery ſhould alſo be uſed as a general term, ſignifying the moving and operative parts of any machine or engine whatever, and its ſynonimous term mechaniſm be applied to the moſt delicate machinery, ſuch as the parts of watches and mathematical inſtruments, or to the moſt delicate parts of any other machine, as the machinery of a flour-mill, or ſawing-mill; the mechaniſm of a clock, watch, orrery, &c.

Let the term *engine* be reſtricted to ſuch machines as have ſome relation to hydraulics or pneumatics, or, in ſhort, where their operations depend upon, or actuate fluids; as a ſteam engine, a water engine, pumping engine, blowing engine, preſſure engine, and fire extinguiſhing engine.

Mill ſhould be applied to large and powerful compound machines, or ſyſtems of machines; including their firſt mover in the term; as a cotton mill, which contains a vaſt number of different machines, and alſo the water wheel, or ſteam engine, which actuates them all; ſo likewiſe, an iron mill, copper mill, rolling mill, grinding mill, logwood mill, worſted mill, &c. &c.

Corn mill, or *flour mill*, is, in ſome degree, an exception to our definition, becauſe in the early ſtages of ſociety it was the only mill in uſe, and hence the term became particularly attached to it; and any machine for grinding or reducing to powder is called a mill, as a coffee mill, bark mill, colour mill, malt mill, &c. though, in ſtrictneſs, theſe ſhould be called machines.

In this claſſification, we have ſtudied to infringe as little as poſſible upon the diſtinctions which have been made by cuſtom, and confirmed by the uſage of mechanics themſelves, though not invariably, for they have dividing engines, cutting engines, and many others which ſhould be machines.

MACHINERY.

The practical application of mechanics to the conſtruction of machinery, is a ſubject of the utmoſt importance to the welfare of our country, depending ſo materially as it does upon commerce, which is derived chiefly from our manufactures; and theſe owe the pre-eminence they have over other nations to the general introduction of machinery, which has taken place within theſe forty years, to abridge manual labour in every department, and in every trifling operation: it is to this ſource we muſt look for the increaſe of property of every deſcription, as the introduction of every machine is a real creation of all the work it will perform, without the addition of farther increaſe of human labour. An idea is very generally entertained, that machinery is prejudicial to the intereſt of mankind, as far as it tends to diminiſh the value of that labour by which the lower claſſes of ſociety can alone purchaſe the means of ſubſiſtence: this idea is, however, founded on error, as applied to any ſuppoſed injury ſociety in general can ſuſtain, though individuals whoſe labours are ſuperſeded by machines, will ſuffer inconvenience for a time, yet it is only for a time, and ſo long as they, or others more intelligent, ſhall diſcover a new channel for the exertion of their induſtry. As machines tend to increaſe the quantities of thoſe luxuries and neceſſaries of life which mankind are ſo anxious to obtain, it only requires that an equitable diviſion of theſe benefits ſhould be made to obviate every objection, and really improve the condition of all claſſes; a retroſpect of the laſt forty years ſhews the truth of this obſervation, for though ſo many machines have been employed in all trades and manufactures as probably to do more work than the whole population could do previous to that period, yet the value of human labour has, notwithſtanding, increaſed in the ſame proportion as other articles have advanced in price.

We ſhall, in this article, enter into ſome general obſervations upon the conſtruction of machinery, and particularly point out ſuch contrivances as ſeem applicable to other purpoſes than thoſe for which their inventors have employed them; and we ſhall give, as examples of practical machinery, a deſcription of the famous block machines at Portſmouth, which contain many new contrivances. We were unable to introduce theſe under the article Block, as the machines were not erected at the time that article was printed.

The grand object of all mechaniſm, or machinery, is to convey and modify the motion of the firſt mover of the machine, and communicate it in a proper manner to the ſubject to be operated upon: thus, the ſlow rotative motion of a water-wheel is, by the machinery of cranks, levers, and toothed wheels, converted into a rapid reciprocating motion for working ſawing machines, and the velocity of the motion is increaſed or diminiſhed, as the occaſion requires either great power or great ſpeed. In like manner, the rectilinear motion of the piſton rod of a ſteam engine is, by the machinery of parallel levers, working-beam, connecting-rod, crank and fly-wheel, converted into a rotative motion; and this motion can again, by the machinery of wheel-work, be adapted, either in velocity or power, to work grinding-ſtones, circular ſaws, threſhing-mills, and other ſimilar machines which require great velocity; or flatting mills, boring machines, raſping machines for logwood, lead-pipe drawing machines, &c. which require great power to give them motion, and are, therefore, performed with a leſs velocity. Machinery is, therefore, the organs by which motion is altered in its velocity, its period, and direction, and thus adapted to any purpoſe. All machinery will be found, upon minute inveſtigation, to be only modifications of the ſix mechanical powers: the greateſt number will be found to conſiſt chiefly of parts which have a motion of rotation round fixed axes, and derive all their energy from levers virtually contained in them: thus the pullies, wheel and axle, are only modifications of the lever, and the ſcrew is compounded of the lever with a variety of the inclined plane or wedge, ſo that the number of mechanical powers may be reduced to two, which aſſume an infinite variety of forms and motions. The theory and manner of calculating their effects will be found under Mechanics.

In contriving any machinery, the engineer ſhould always remember that nothing contributes more to the perfection of a machine, eſpecially if it is maſſive and ponderous, than great uniformity of motion. Every irregularity of motion waſtes ſome of the impelling power; and it is only the greateſt of the varying velocity which is equal to that which the machine would acquire if moving uniformly throughout; for while the motion accelerates, the impelling force is greater than what balances the reſiſtance then actually oppoſed to it, and the velocity is leſs than what the machine would acquire if moving uniformly; and when the machine attains its greateſt velocity, it attains it becauſe the power is then not acting againſt the whole reſiſtance. In both of theſe ſituations, therefore, the performance of the machine is leſs than if the power and reſiſtance conſtantly bore the ſame relation to each other, in which caſe it would move uniformly.

Every attention ſhould, therefore, be given to this, and we ſhould endeavour to remove all cauſe of irregularity through the whole machine. There are continual returns of ſtrains and jolts from the inertia of the different parts acting in oppoſite direction. Although the whole momenta may always balance each other, yet the general motion is hobbling, and the points of ſupport are ſtrained. A great engine, ſo conſtructed, commonly cauſes the building to tremble; but when uniform motion pervades the whole machine, the inertia of each part tends to preſerve this uniformity, and all goes ſmoothly. It is alſo deſerving of remark, that when the communications are ſo contrived, that the uniform motion of one part produces uniform motion to the next, the preſſures at the communicating points remain conſtant or invariable. Now the accompliſhing of this is generally within the reach of mechanics, and the engineer ſhould adapt his machinery to the particular caſe before him.

In the machinery for modifying and adapting a rotatory motion, the firſt which preſents itſelf is the communication by means of toothed wheels acting on each other. This is the moſt general method in machinery, becauſe it tranſmits the motion with certainty and accuracy, and if the teeth are properly formed, wheels, perhaps, conſume leſs force in friction than any other method; but this is a ſubject underſtood by few mechanics. In the treatiſes on the conſtruction of mills, and other works of this kind, are many inſtructions for the formation of the teeth of wheels, and almoſt every noted millwright has his own noſtrums; but they are moſt of them defective in principle, or at leaſt they are only correct in certain caſes, which have by experiment or theory been determined, and are extremely fallacious when applied indifferently for all caſes, as is the millwright's cuſtom. An inveſtigation of this ſubject, as applied to delicate mechaniſm, where accuracy rather than ſtrength is the object, will be found in our article Clock *Work*, and we propoſe to give ſome further applications of thoſe principles to wheels of large dimenſions under Mill *Work*.

In the formation of the teeth of wheels, a ſmall deviation from the perfect form is not, perhaps, of very great importance, except in caſes where a very large wheel drives a very ſmall one, a caſe the judicious engineer ſhould always avoid: the grand point to be attended to, is to adopt ſuch a conſtruction as will inſure all the teeth of a wheel being preciſely equal, and to make as great a number of them as the ſtrength will admit. This will cauſe ſeveral teeth to be in action at once, and make the communication of the motion extremely ſmooth and uniform. To obtain ſtrength in the cogs when they are made fine, the width or thickneſs of the wheel muſt be increaſed; and this is one of the greateſt practical improvements which has been made in machinery for theſe laſt twenty years. Formerly the beſt engineers, ſuch as Smeaton, directed the teeth of large cog-wheels to be four and five inches diſtant from each other, or *pitch*, as the millwrights term it. Such wheels always act unequally upon each other in conſequence of the point of contact of the large cogs conſtantly altering its poſition, becoming alternately nearer or farther from the centre of one or other of the wheels; and this, tending to increaſe the acting radius of one, whilſt it diminiſhes the other, cauſes their velocity and powers to vary at every cog that paſſes by, and the machine works by ſtarts and jerks. The wheel-work of modern machinery is conſtructed with fine cogs, ſeldom more than one and a half or two inches pitch, and as much length of cog, or breadth of the wheel, as will make them ſufficiently ſtrong. We have ſeen ſome wheels in a large cotton mill which bore a ſtrain equal to thirty horſes' power, in which they were nine and twelve inches broad upon the face. Cog-wheels are found to work moſt ſmoothly when the teeth of the large wheel are made of hard wood, and the teeth of the ſmall one made of caſt iron, the acting ſurfaces being dreſſed or filed ſmooth and to the true figure. A mechanic, in contriving any machinery, ſhould always bear in mind, that where he introduces cog-wheels, they ſhould be as large in their diameters as is conſiſtent with other circumſtances, becauſe this allows the teeth to be made finer in proportion to the power they are to bear, than if they were of ſmaller radii; and the teeth, therefore, nearer the centre: it alſo occaſions leſs preſſure or drift upon the centre, and the wear of the whole will be equable. Another circumſtance is worth notice, and ſhould always be attended to, where it will not interfere with more important conſiderations; this is, the direction in which any force is given to, and taken from, any piece of wheel-work: ſuppoſe, for inſtance, a water-wheel turning its axis, upon which is fixed a cog-wheel to give motion to a ſecond wheel, for the purpoſe of driving any machinery; now if this ſecond cog-wheel is applied on that ſide of the firſt cog-wheel which is aſcending, it will be oppoſite to that ſide of the wheel which is loaded with water, and is conſequently deſcending. In this ſtate the gudgeons of the water-wheel will have to bear (in ſome caſes) double the ſtrain of the power of the machine; becauſe the power, which is the weight of the water, is applied on one ſide the centre of the wheel, and is taken off by turning the ſecond cog-wheel on the other ſide: the centre, or fulcrum, therefore, bears the whole power, and alſo the re-action to that power, in addition to the weight of its own parts; in the ſame manner as the fulcrum of a ſteelyard or balance beam bears the whole of the weight ſuſpended from either end, and its own weight alſo. On the other hand, ſuppoſe the ſecond wheel applied on the deſcending ſide of the water wheel, this being on the ſame ſide of the centre, the preſſure thereon will be far leſs than the power of the machine. In ſome caſes (but not in a water-wheel), by the proper arrangement of the wheel-work, the power may be made to operate to lift the centres, and thus in part relieve them from the weight of the wheel, ſo as actually to diminiſh the preſſure of friction of the pivots, when, by a contrary application, it would have increaſed it in the ſame degree. Similar advantages will attend the precaution of adapting the poſitions of different wheels upon their ſhafts to the different weights or ſtrains they have to bear, ſo that the gudgeons at the two ends of any ſhaft may have an equal drift or preſſure upon them. This will cauſe them to wear equally, and to have leſs friction, becauſe they may be made ſmaller than where no ſuch care is taken, ſtill having ſufficient ſtrength. It is accompliſhed by conſidering the drift or preſſure upon the centre of every wheel upon any axis, and placing the two gudgeons or pivots of the axis at a diſtance from each of the wheels, proportionate to the drift upon its centre. Thus, ſuppoſe a ſhaft has a cog-wheel fixed upon it, and a ſmall wheel or pinion alſo fixed upon it at ſome diſtance from the wheel, the power is given to the axis by wheel-work operating upon the teeth of the pinion, and the re-action to this power is given by ſome machinery which the teeth of the large wheel actuates. In this caſe the drift on the centre of the pinion will be very conſiderable, becauſe the power is applied near the centre of the axis; but the wheel tranſmitting the power at a greater radius, will, perhaps, have much leſs drift on its centre (the proportion depending in ſome degree upon the direction in which the power and re-action are applied, as ſtated in our laſt obſervation): if this is the caſe, the gudgeon at that end of the ſhaft, where the pinion is placed, ſhould be lengthened out, ſo as to give the bearing point at a greater diſtance from it than the wheel, which ſhould have its gudgeon placed much nearer to it, becauſe leſs ſtrain is to be borne. By this means the drift upon the two ends of the ſhaft will be equally divided between them: and though this proportion of the centre cannot be always accompliſhed without inconvenience, the engineer ſhould always have it in view; and then, where it is not practicable, he ſhould attain the ſame end, by apportioning the ſtrength or diameter of the gudgeons to the relative ſtrains they have to bear.

An endleſs belt or ſtrap is a very general method of tranſmitting rotatory motion: it is uſually employed in caſes where a very quick motion is to be created, and the re-action to be overcome is nearly equable. In ſuch caſes it has the advantage of wheel-work from its ſimplicity and the eaſe of its motion. Some curious properties belong to the endleſs ſtrap, *viz.* that the pulley or rigger it works upon muſt be largeſt in the middle, that is, the diameter muſt be greater in the middle of the pulley than at the edges, becauſe the ſtrap always rides on to the largeſt diameter of the pulley, and if this is not in the centre it will ſlip off at one ſide. It is not eaſy to give any ſatisfactory explanation of this fact, nor of another, that if, by accident, one of the pullies is ſtopped while the ſtrap is urged round by the motion of the other, it inſtantly flies off its pulley, unleſs the edge of the pulley ſhould be much wider than the ſtrap. This property is a great recommendation of it for ſome purpoſes, ſuch as threſhing mills, flour-dreſſing machines, lathes, cotton machines, &c. where any thing accidentally ſtopping the machines would deſtroy them if driven by wheel-work, but the ſtrap ſlips round, and very ſoon comes off, ſo as to avoid all further danger. Belts of *girt-web*, ſuch as are uſed for ſaddle girts, are ſometimes uſed inſtead of leather ſtraps, though theſe are undoubtedly preferable. The ſtrap ſhould be dreſſed to an equal thickneſs and breadth throughout, and the ends very neatly joined; that is, of the ſame thickneſs there as at every other part. It is ſometimes done by ſewing, but the beſt method is by gluing them together, with a glue compounded of Iriſh glue, iſinglaſs, ale grounds, and boiled linſeed oil. The two ends being tapered away and overlapped are united with this cement, and will be as flexible as any other part, but ſo ſtrong that it will tear to pieces in any part rather than at the joint. A tool for equalizing the thickneſs and breadth of the ſtraps for belts is deſcribed in the Tranſactions of the Society of Arts, vol. xxviii. p. 192, invented by Mr. Aubrey. They will by this means be rendered very correct, for nothing can be more unpleaſant in machinery than the joint and thick places in the endleſs ſtraps jerking over the riggers, and cauſing a violent drift upon the centres every time by the increaſed tenſion of the ſtrap.

A mechanic, in calculating any extenſive piece of machinery which is to depend upon ſtraps for the communication of its motions, particularly if they are of great length to convey their motion to a conſiderable diſtance, and have much ſtrain upon them, ſhould always conſider that ſuch machinery will loſe ſome of its velocity; that the wheels, which are turned by ſtraps, will never make quite ſo many revolutions as they ought to do from a calculation of their diameters. This is generally ſuppoſed to ariſe from the ſtrap ſlipping, in ſome degree, upon the ſurface of the wheels it paſſes over, but we are inclined to ſuſpect that it ariſes from another cauſe which has not been inveſtigated, *viz.* the elaſticity of the ſtrap: for inſtance, ſuppoſe that the diſtance between two wheels connected by a ſtrap is ten feet, and that the ſtrain upon the ſtrap is ſuch as to ſtretch or extend it two inches in that length on the ſide which bears the ſtrain (called by mechanics the leading ſide), on the other, or returning ſide, there will be no ſtrain, and therefore the ſtrap will return to its original length. In ſuch a caſe the wheel which is driven will loſe in its motion two inches in every ten feet, becauſe the ſtrap gives out that quantity in leading to the wheel, but takes it up again in returning, as ſoon as the ſtrain is removed from it.

Small machines are ſometimes turned by a catgut band, the ends of which are united by a ſmall ſteel hook and eye, the hook being faſtened at one end and the eyes at the other. They are made with tubes, for the reception of the ends of the band, which are tapped with a ſcrew withinſide, and the band being tapered and ſcrewed into the tube holds very faſt. But to prevent it drawing out, a ſmall quantity of roſin ſhould be applied to the end of the band which projects through the tube, and a hot wire being touched to it ſinges and hardens the end, that it will never draw out of the tube. This method is conſtantly uſed in ſmall lathes, and works very neatly. The pullies for a catgut-band ſhould always be cut with a ſharp angular groove, for the reception of the band, and it ſhould not touch the bottom of it, or it will be liable to ſlip. For the ſame reaſon, the pullies are beſt made of wood, becauſe metals ſoon acquire a poliſh, which prevent the band holding firmly upon it. The wood ſhould be cut with its grain acroſs the direction of the band, that every part of the circumference may be of a ſimilar texture.

Endleſs chains are ſometimes uſed to communicate motion of wheels, and frequently cogs are formed on the wheels to be received into the links of the chains. This method is very practicable on particular occaſions, and though it has not advantages to put it in competition with cog-wheels acting upon each other when they can be applied, it is in many inſtances a valuable reſource to the engineer to convey motion to ſome diſtance when it requires to be accurate, and where it would injure the operation of the machine if any motion was loſt by the ſlipping of bands. In making ſuch chains the greateſt care is neceſſary to have all the links preciſely of one length, and the cogs very accurately fitted to them, or a great friction will be cauſed by the cogs forcing themſelves into ſpaces not exactly ſituated to receive them. The beſt way is to make the links in the manner of watch or clock chains, with iron plates, and holes drilled through them at equal diſtances, to receive croſs pins upon which the cogs are to act. By this means the lengths may be made far more accurately than by bending the iron in the manner of common chain links.

Mr. Nicholſon has deſcribed a ſpinning-wheel for children, at a charity-ſchool, in which a large horizontal wheel, with a ſlip of buff leather glued on its upper ſurface near the outer edge, drove twelve ſpindles, at which the ſame number of children ſat.

The ſpindles had each a ſmall roller, likewiſe faced with leather, and were capable, by an eaſy and inſtantaneous motion, of being thrown in contact with the large wheel at pleaſure; each child, therefore, could throw her own part of the apparatus into work, or cauſe it to ſtop as often or as long as ſhe pleaſed.

The winding bobbins for yarn at the cotton mills operate on the ſame ſimple and elegant principles, which poſſeſſes the advantages of drawing the thread with an equal velocity, whatever may be the quantity of the bobbins, and cannot break it. The ſame mode of communication has been adopted in large work by Mr. Taylor, of Southampton, in his ſaw mills. In this the wheels acted upon each other by the contact of the end grain of wood inſtead of cogs. The whole made very little noiſe and wore very well: it was in uſe nearly twenty years. There is of conſequence a contrivance to make the wheels bear firm againſt each other, either by wedges at the ſocket or by levers. This principle and method of tranſmitting mechanic power certainly deſerve attention; particularly as the cuſtomary mode by means of teeth requires much ſkill and care in the execution; and after all wants frequent repair. We have ſeen it applied to a threſhing machine, a ſmall wheel on the threſhing drum being applied in contact with the large wheel which gave motion to it, and a preſſure ſufficient to make it turn the machine was given by loading the ſocket for the ſpindle of the drum with a conſiderable weight. The ſame principle is capable of communicating motion with great accuracy when no force is required, as will be ſeen on a peruſal of Mr. Troughton's ingenious method of dividing aſtronomical inſtruments. See GRADUATION.

The conſtruction of bearings, pivots, gudgeons, or centres, of ſpindles, as they are indifferently termed, is a moſt important point; theſe parts being the principal ſeats of that friction which is the deſtruction of all machinery. Pivots are always made of iron or ſteel, both becauſe theſe ſubſtances are better adapted for rubbing ſurfaces, and that their ſtrength admits the pivot being as ſmall as poſſible; the bearing, or bed to receive the gudgeons or pivots, ſhould be of a ſofter metal, as braſs, tin, or zinc, and kept well ſupplied with oil when at work. Hardened ſteel is a moſt admirable ſubſtance for pivots, which have a great ſtrain to bear, and a rapid motion. The bearing or bed may alſo be made of the ſame material, and is the only inſtance where two bodies, having friction againſt each other, can with propriety be made of the ſame ſubſtance: for it is found, that where iron or ſoft ſteel ſurfaces are worked with a friction againſt parts of the ſame ſubſtances, the friction and abraſion are far greater than when a ſofter material, as braſs, tin, hard wood, ivory, horn, &c. is uſed. The great difficulty of making hard ſteel pivots to ſpindles is the only reaſon they are not generally uſed; but there are ſome caſes, in which nothing elſe can be employed: where ſteadineſs and accuracy of motion are required, and great velocity at the ſame time. To obtain this accuracy, it is neceſſary that the pivot ſhould be fitted, and kept in accurate contact with the interior ſurface of its ſocket or pivot-hole, and this will preſent a ſufficient acceſs of oil, to prevent any other ſpindle, than one of hardened ſteel, from burning or heating by the friction, when in rapid motion; and the expanſion occaſioned by this heat increaſes the preſſure and the friction, till the pivot becomes fixed in its ſocket, and will rather twiſt off than turn round in it. The ſpindle for a turning lathe muſt always be of hard ſteel; and even then, a failure of the ſupply of oil for a moment, will cauſe it to burn into the collar. Circular ſaw-ſpindles are frequently burnt in the ſame manner; their motion being very quick.

The beſt form of a gudgeon or pivot for a ſpindle, is that of a cylinder, with a flat ſhoulder, to prevent it from ſhifting its poſition endways. This form will bear moſt fairly and ſteadily; but it is neceſſary that the ſocket, or braſs which contains the pivot, ſhould be made in two halves, and put together with ſcrews, that the halves may be ſcrewed cloſer as the ſocket enlarges by wearing: but as this is only an imperfect method, becauſe the pivot can never fit accurately after having been worn, a conical form is uſed for the pivots of axles requiring great accuracy, as theſe may be always made to fill their ſockets, by preſſing the cone farther into its ſocket. The cone is uſed in many turning lathes, whilſt others are made very nearly cylindrical, with a ſhoulder; and as the collar is of hard ſteel, they do not wear in any ſenſible degree. Their advantage over the cone is, that they have no drift endways upon the oppoſite centre, as the cone has; though this is ſo ſlight in an acute cone, as to be of no importance in ſmall machinery. In heavy works, ſuch as the gudgeons of water-wheels, a conical figure would be highly improper, and has no advantage to recommend it; as ſuch gudgeons ſeldom have any braſs ſcrewed down over them, their own weight being ſufficient to keep them down, and they always fit true as they wear away. The moſt accurate and ſimple of all pivots is that which is ſimilar to a piece of work, while turning in a lathe; the axis having a ſmall hole made in each end of it, and the ſupports formed by ſharp conical points, received into the holes; and one of them muſt be adjuſtable by a ſcrew, to make it always fit the length of the ſpindle. It is uſual to make the conical points on the ends of two ſcrews, either of which may then be adjuſted. The ſame thing may be accompliſhed by making conical points at the ends of the ſpindle, and forming the holes for its reception in ends of the two fixed ſcrews, which can at all times be ſcrewed up as the parts wear. It is the moſt perfect of all methods, but is not adapted to bear any great ſtrain, becauſe the ſcrews will get looſe, and all the objections to the conical ſpindle apply to it.

The pivot at the lower end of a vertical ſhaft, which has a great weight to ſuſtain, as in a heavy horſe-wheel, is very properly made of a hemiſpherical figure, and received into a proper cavity. A cylindrical pivot, having a flat end, is frequently uſed for large and heavy upright axes; but it is difficult to keep oil ſupplied to them, as the great weight preſſes it out from between the acting ſurfaces, and the gudgeon burns. To avoid this, ſome mechanics make a cleft acroſs the lower face of the gudgeon, exactly in the manner of a ſcrew-head. This getting full of oil, is conſtantly ſupplied to the acting ſurfaces.

We have ſeen an horizontal windmill, having a vertical axis 100 feet high, with ſails and wheels of immenſe weight, all bearing upon one pivot. This was with the greateſt difficulty kept in order; and it was neceſſary to keep a ſmall ſtream of cold water always running into a pan, which ſurrounded the gudgeon, to keep it cold. This method of watering, inſtead of oiling, a gudgeon is alſo uſed in paper-mills; but it cannot be recommended as a good method.

Friction-rollers are frequently uſed for ſupporting gudgeons, and, if made with great care, have the leaſt friction which can be conceived; but they are liable to get out of order, if not made with extreme accuracy. See MILL-*Work*.

A great number of machines depend upon reciprocating motions, ſuch as pump-mills, ſaw-mills, &c. Where the firſt mover has a circular motion, as a water-wheel, the reciprocating movement will be moſt conveniently produced by means of a crank; becauſe it commences the change of motion by degrees, and does not ſuddenly urge the parts into motion in a contrary direction; nor ſuddenly check the movement again, but effects both changes without violence. It is proper, in ſuch caſes, to regulate the motion of the firſt mover by a fly-wheel, otherwiſe the reſiſtance of the work, at the inſtant of the change of motion, is ſo ſmall, that the machine would accelerate in that period, and then be checked again. The ſame may be accompliſhed by having ſeveral of the reciprocating movements and theſe act alternately, that when one requires the moſt power, the others take the leaſt, ſo as to equalize the reſiſtance to the firſt mover, and make the motion uniform. All reciprocating machines labour under great diſadvantages, from the circumſtance that a great maſs of matter muſt be put in motion, and this motion deſtroyed again. Thus, in a ſingle pump forcing water through a great height of pipes, the column of water is, at every ſtroke the pump makes, put in rapid motion, which is wholly loſt during the return of the pump-bucket for another ſtroke, when freſh impetus muſt be given to the water: now by applying a double acting pump, or two or three pumps acting at intervals, and the water regulated by an air-veſſel, the motion will be very eaſy, becauſe the column of water will be in conſtant motion through the pipes, and the momentum once given to it will continue as long as the machine is at work, inſtead of requiring a repetition of it at every ſtroke.

In every machine, the action of the moving power is transferred to the working point, through the parts of the machinery, which are material, inert, and heavy; or, to deſcribe it more accurately, before the neceſſary force can be excited at the working point of the machine, the various connecting forces muſt be exerted in the different parts of the machine: and in order that the working point may follow out the impreſſion already made, all the connecting parts or limbs of the machine muſt be moved in different directions, and with different velocities. Force is neceſſary for thus changing the ſtate of all this matter, and frequently a very conſiderable force. Time muſt alſo elapſe before all this can be accompliſhed. This often conſumes, and really waſtes, a great part of the impelling power. Thus, in a crane worked by men walking in a wheel, it acquires motion by ſlow degrees; becauſe, in order to give ſufficient room for the action of the number of men or cattle that are neceſſary, a very capacious wheel muſt be employed, containing a great quantity of inert matter. All of this muſt be put in motion by a very moderate preponderance of the men: it accelerates ſlowly, and the load is raiſed. When it has attained the required height, all this matter, now in conſiderable motion, muſt be ſtopped. This cannot be done in an inſtant, with a jolt, which would be very inconvenient, and even hurtful: it is therefore brought to reſt gradually. This alſo conſumes time. Nay, the wheel muſt get a motion in the contrary direction, that the load may be lowered into the cart or lighter; and this can only be accompliſhed by degrees. Then the tackle muſt be lowered down again for another load, which alſo muſt be done gradually. All this waſtes a great deal both of time and force, and renders a walking-wheel a very improper form for the firſt mover of a crane, or any machine whoſe uſe requires ſuch frequent changes of motion. The ſame thing obtains, although in a lower degree, in the ſteam-engine, where the great beam and pump-rods, ſometimes weighing many tons, muſt be made to acquire a very briſk motion in oppoſite directions, twice in every working ſtroke. It operates in a greater or a leſs degree, in all engines which have a reciprocating motion in any of their parts. Pump-mills are of neceſſity ſubjected to this inconvenience. In the famous engine at Marly, about $\frac{12}{26}$ths of the whole moving power of ſome of the water-wheels is employed in giving a reciprocating motion to a ſet of rods and chains, which extend from the wheels to a ciſtern about three-fourths of a mile diſtant, where they work a ſet of pumps: thus the engine is, by ſuch injudicious conſtruction, a monument of magnificence, and the ſtruggle of ignorance with the unchangeable laws of nature. In machines, all the parts of which continue the direction of their motion unchanged, the inertia of a great maſs of matter does no harm; but, on the contrary, contributes to preſerve the ſteadineſs of the motion, in ſpite of ſmall inequalities of power or reſiſtance, or unavoidable irregularities of force in the interior part. But in all reciprocations, it is highly prejudicial to the performance; and, therefore, conſtructions which admit ſuch reciprocation without neceſſity, are avoided by all the intelligent engineers.

In many machines, but generally in ſmall works, what are called hearts, camms, ſnails, excentric wheels, &c. are a very excellent method of producing ſlight reciprocating movements to levers. From the rotatory motion of an axis, they have the great advantage of admitting any modification of the motion, to act ſuddenly or gradually, in either direction, at the pleaſure of the maker. This is done, by wheels of a particular form, faſtened upon an axis, and levers applied in contact with their circumferences, which receive a motion in proportion as the different radii of the wheels alter their lengths; and if, at any point of the motion, the lever is to be in a ſtate of reſt, the periphery of the wheel is, during that period, made a circular arc, and concentric with the axis. From the facility of producing any motion whatever by camms, it is an univerſal method, and applicable to all ſubjects; but ſtill has objections, which will induce the engineer to neglect it in thoſe inſtances, where any other movement will anſwer the ſame purpoſe. Theſe objections are the great friction, and wear of the camms, which ſoon unfits them for accurate motion: this may in ſome meaſure be obviated by applying rollers in the ends of the levers, to receive the contact of the camm. Another objection is, that the camm is unfit for producing a double motion, becauſe a ſpring or weight muſt be introduced to return the lever, and always keep it in contact with the camm. Now if this ſpring is only uſed to return the lever, it will operate very well; but if it is made ſo ſtrong as to effect any operation of the machine, the friction will be great, and be a ſerious objection to the uſe of camms.

The principles of theſe movements, and practical directions for conſtructing camms for any kind of movement, is fully explained in our article Diagonal *Motion*, which renders it unneceſſary to enlarge upon the ſubject in this place. Camms are uſed on a large ſcale in rolling-mills, for working the ſhears with which large iron bars are clipped into lengths. They are alſo employed in the machine for punching holes through the iron plates for boilers, weaving machines, &c.; and are in common uſe in the blowing machine uſed in iron forges; but it is a very injudicious application, and a common crank would be much better.

We once with great pleaſure contemplated a very complicated machine, in which were many reciprocating parts neceſſarily operating only whilſt moving in one direction; in the other, they had merely to return to repeat their operations. To produce this reciprocation, the inventor applied a crank, which was cauſed to revolve by the action of a pair of elliptical cog-wheels, each balanced on an axis paſſing through one of its foci. In this conſtruction, the motion of the driven wheel and the crank it carried, was exceedingly variable, but by equal increments of alternate acceleration and retardation. Thus when the long radius of the firſt wheel was operating, it met the ſhorteſt radius of the other, therefore giving it and alſo the crank a rapid motion: in this ſtate, the crank was returning to repeat its ſtroke, and with a quick ſtroke; but by the time it had completed half a revolution, the action was reverſed, the ſhort radius of the firſt wheel acting upon the long radius of the ſecond, which was therefore with its crank at the ſloweſt point of its movement: but the decreaſe of the motion, from the quickeſt to the ſloweſt point of its revolution, being effected by equal increments, gave no ſhock to the machinery. The crank was of courſe, during the ſlow half of its movement, performing its work; and in the quick period, returning to fetch its ſtroke. By this judicious arrangement, the reſiſtance to the firſt movement was very nearly equable: for when it had work to perform, the wheel-work gained a power upon the working point; but in returning, it cauſed it to urge the working point with ſuch an increaſed velocity, as in ſome degree counterbalanced the diminiſhed reſiſtance: but in this, no loſs was occaſioned, becauſe this increaſed velocity ſhortened the period of inaction haſtening the return to a ſituation for repeating its operation.

Theſe elliptical wheels are, in the hands of an able mechanic, a very uſeful contrivance, but they have not been much uſed in machinery, from the difficulties of forming their teeth with preciſion. In the Cometarium, (ſee that article,) they are introduced to repreſent the elliptic motions of comets, and we have ſeen two inſtances of their being uſed in large machines, where they operated with as much facility as circular wheels. It is to be obſerved, that a ſmall excentricity of the ellipſe, conſequently a ſlight deviation from the circular figure, will produce a great inequality of their motion, becauſe the increaſe of the acting radius of one wheel, is attended with a correſpondent decreaſe of the other, ſo that to produce almoſt any differences of motion which can be required in practice, the excentricity of the wheels will be ſuch as can eaſily be accompliſhed, and as will work with each other ſmoothly and accurately. When heavy ſtampers are to be raiſed in order to drop on the matter to be pounded, the wipers, by which they are lifted, ſhould be made of ſuch a form that the ſtamper may be raiſed by an uniform preſſure, or with a motion almoſt imperceptible at firſt. If this is not attended to, and the wiper is only a pin ſticking out from the axis, the ſtamper is forced into motion at once. This occaſions a violent jolt to the machine, and great ſtrains on its moving parts and their points of ſupport: whereas, when they are gradually lifted at firſt, the inequality of deſultory motion is never felt at the impelled point of the machine.

We have ſeen piſtons of pumps moved by means of a double rack on the piſton rod: a half wheel takes hold of one rack and raiſes it to the required height. The moment the half wheel has quitted that ſide of the rack, it lays hold of the other ſide and forces the piſton down again. This has been propoſed as a great improvement, by correcting the unequable motion of the piſton, moved in the common way by a crank motion; but it occaſions ſuch abrupt changes of motion, that the machine is ſhaken by jolts. Indeed, if the movements were accurately executed, the machine would be ſoon ſhaken to pieces, if the parts did not give way by bending and yielding. Accordingly we have always obſerved that this motion ſoon failed, and was changed for one that was more ſmooth: a judicious engineer will avoid all ſuch ſudden changes of motion, eſpecially in any ponderous part of a machine.

When ſeveral ſtampers, piſtons, or other reciprocal movers are to be raiſed and depreſſed, common ſenſe teaches us to diſtribute their times of action in an uniform manner, ſo that the machine may always be equally loaded with work. When this is done, and the obſervations in the preceding paragraph attended to, the machine may be made to move, almoſt as ſmoothly as if there were no reciprocations in it. Nothing ſhews the ingenuity of the engineer more, than the artful, yet ſimple and effectual contrivances, for obviating thoſe difficulties that unavoidably ariſe from the very nature of the work to be performed by the machine, or in the power employed to actuate it.

In the contrivance of machinery, an engineer muſt not be tied down by too many inviolable maxims, becauſe thoſe contrivances which are the moſt improper in ſome ſituations will be the beſt of all in other caſes. There is great room for ingenuity and good judgment in the management of the moving power, when it is ſuch as cannot immediately produce the kind of motion required for effecting the purpoſe. We mentioned the converſion of the continued rotation of an axis into the reciprocating motion of a piſton, and the improvement which was thought to have been made on the common and obvious contrivance of a crank, by ſubſtituting a double rack on the piſton rod, and the inconvenience ariſing from the jolts occaſioned by this change. We have been informed of a great forge, where the engineer, in order to avoid the ſame inconvenience ariſing from the abrupt motion given to the great ſledge hammer of ſeven hundred weight, reſiſting with a five-fold momentum, formed the wipers for lifting it into ſpirals, which communicated motion to the hammer with ſcarcely any jolts whatever: but the reſult was, that the hammer roſe no higher than it had been raiſed in contact with the wiper, and then fell on the iron bloom, with very little effect. The cauſe of its inefficiency was not gueſſed at; but it was removed, and wipers of the common form were put in place of the ſpirals.

In this operation the rapid motion of the hammer is abſolutely neceſſary; it is not enough to lift it up, it muſt be raiſed up ſo as to fly higher than the wiper lifts it, and to ſtrike with great force the ſtrong oaken ſpring which is placed in its way. It compreſſes this ſpring, and is reflected by it with a conſiderable velocity, ſo as to hit the iron as if it had fallen from a great height: had it been allowed to fly to that height it would have fallen upon the iron with ſomewhat more force (becauſe no oaken ſpring is perfectly elaſtic); but this would have required more than twice the time.

In employing a power which of neceſſity reciprocates, to drive machinery which requires a continuous motion (as in applying the ſteam engine to a cotton or corn grinding mill), there alſo occur great difficulties. The neceſſity of reciprocation in the firſt mover waſtes much power, becauſe the inſtrument which communicates ſuch an enormous force muſt be extremely ſtrong, and be well ſupported. The impelling power is waſted in imparting, and afterwards deſtroying a vaſt quantity of motion in the working beam. The ſkilful engineer will attend to this, and do his utmoſt to procure the neceſſary ſtrength of this lever, without making it a vaſt load of inert matter. He will alſo remark, that all the ſtrains on it, and on its ſupports, are changing their directions in every ſtroke. This requires particular attention to the manner of ſupporting it: if we obſerve the old ſteam engines which have been long erected, we ſee that they have uniformly ſhaken the building to pieces. This has been owing to the ignorance or inattention of the engineer in this particular; they are much more judiciouſly erected now, experience having taught the moſt ignorant that no building can withſtand their deſultory and oppoſite jolts, and that the great movements muſt be ſupported by a frame work of wood or iron, independent of the building of maſonry which contains it. The gudgeons of a water wheel ſhould never reſt on the wall of the building; it ſhakes it, and if ſet to work ſoon after the building has been erected, it prevents the mortar from taking firm bond, perhaps by ſhattering the calcareous cryſtals as they form.

When the engineer is obliged to reſt the gudgeons in this way, they ſhould be ſupported by a block of oak laid a little hollow: this ſoftens all tremors, like the ſprings of a wheel carriage. This practice would be very ſerviceable in many other parts of the conſtruction. It will frequently conduce to the good performance of an engine, to make the action of the reſiſting work, unequable, and accommodated to the inequalities of the impelling power. This will produce a more uniform motion in machines, in which the momentum of inertia is inconſiderable. There are ſome beautiful ſpecimens of this kind of adjuſtment in the mechaniſm of animal bodies.

In many compound machines it is of conſequence to be able to detach part of the movements while the others continue in motion. Thus in cotton-ſpinning machines, it is neceſſary to be able to caſt off or ſtop any ſpindle at pleaſure, without diſturbing the reſt; and in a large mill containing many machines, it is eſſential that any one may be releaſed without interruption to the firſt mover. Such contrivances are called coupling or clutch-boxes: they are effected in various ways, ſome of which are detailed under COUPLING-BOX. But we wiſh here to deſcribe a recent improvement, very generally adopted in cotton and woollen mills; the object of which is to avoid a jerk being given to any machine when it is put in action, from its being ſuddenly urged from a ſtate of reſt to a ſtate of motion: for if the movement is to be rapid, nothing can be more deſtructive to the machine than the violence of the ſhock it receives from the common clutch-box. To avoid this, the arm which gives motion to the machine when the clutch of the running ſpindle is engaged with it, is not fixed faſt upon the ſpindle, but is made in two halves ſcrewed together upon a circular part of the ſpindle, and pinched upon it ſo faſt by the ſcrews, that it will have ſufficient friction to turn the machine round in the ordinary courſe of its work, but ſlips round upon the ſpindle, if the reſiſtance is greater than this friction, which thus becomes the meaſure of the power dealt out to the machine.

Suppoſe a machine of this kind at reſt, the clutch is turned by the firſt mover with a conſiderable velocity, and is ſuddenly connected with the arm above deſcribed: now it requires ſome time (independent of any reſiſtance or work of the machine) to put its parts in motion. In this time the arm ſlips round upon the ſpindle, but the friction acts conſtantly, and with an equable force upon the machine to turn it round. It commences its motion, which gradually accelerates, until it arrives at the ſame velocity as the driving ſpindle, and then the ſlipping of the box ceaſes, and the machine proceeds in an uniform manner: ſtill the box is a very uſeful proviſion in caſe of any accident happening to the machine to ſtop it; by any thing getting into its movements: the box then ſlips round without breaking the works. All machinery, which is expoſed to the chance of great violence, ſhould be provided with ſome equivalent contrivance, which permits the movement to ſlip when the machine is overloaded and would otherwiſe be broken. An inſtance of this will be ſeen in the DREDGING *Engine;* ſee that article. The ſame effect may be produced by conical wheels fitting into each other, in the manner of a valve and its ſeat. One of them being fixed to each ſpindle, will, when they are jambed into each other, communicate the motion, but permits it to ſlip if overloaded. A very ingenious application of this will be found, in the mortiſing machine of the block machines at Portſmouth (ſee MACHINERY *for manufacturing Ships' Blocks*), and another judicious application of it under LOGWOOD *Mill.*

Many other contrivances are in uſe for detaching or uniting motions at pleaſure. In cog-wheels, the ſupports for the gudgeons are ſometimes fitted up ſo as to be moveable, that the wheels can be ſeparated to ſuch a diſtance as to relieve each other's teeth. At other times one of the wheels is fitted on a round part of its axis, and united with it at pleaſure by a clutch-box. Thus the wheels are always in motion, but one of them can be detached at pleaſure from its axis, on which it ſlips freely. Bevelled cog-wheels are eaſily diſengaged, by ſuffering the axis of one to move a little endways, and then their teeth are ſeparated.

Wheels turned by ſtraps are readily connected, or caſt off, by removing the ſtrap, but this is not eaſily done while the wheels are in motion; though ſome dextrous workmen are able to put on the ſtraps when the wheels are going; but it is attended with much difficulty, and great danger, if the motion is quick, of catching the fingers in the ſtrap. We have known an inſtance of a man's arm being torn away at the ſhoulder, by careleſſneſs in performing this operation.

For diſengaging the motion of a ſtrap, the contrivance called the live and dead pulley is very ingenious: it conſiſts of two pullies placed cloſe together upon any axis which is to receive a circular motion. The endleſs ſtrap or band, by encompaſſing one of theſe pullies, gives it a conſtant rotatory motion. Now one of them being fixed faſt upon the ſpindle, and the other ſlipping freely round upon it, gives the means of turning or diſcontinuing the motion of the ſpindle at pleaſure, by ſhifting the ſtrap either upon the live or dead pulley, which, as they are exactly of the ſame ſize, and cloſe to each other upon the ſpindle, is eaſily done. The live pulley is that which is fixed to its axis, ſo called from its cauſing life or motion to the ſpindle, and the machinery appended to it. The dead or idle pulley is that which ſlips upon its ſpindle; therefore, when the ſtrap is cauſed to run upon it, it turns round without giving any motion to the ſpindle. This contrivance is extremely well adapted to give motion to ſmall machinery, from the ſimplicity of its conſtruction, and the facility with which it is put in motion or at reſt. It poſſeſſes alſo another great advantage, *viz.* it occaſions no ſudden ſhock to the machinery at firſt ſtarting, as it does not inſtantly communicate to it the full velocity. To illuſtrate this, ſuppoſe the ſtrap running upon the dead pulley, and the machine therefore at reſt, the leading ſide of the ſtrap is in general conducted through a notch in a piece of board which is fitted in a groove, ſo as to have liberty of ſliding in ſuch a manner that it may conduct the ſtrap to work upon either of the pullies; but this is not neceſſary nor always attended to, for the perſon who attends the machine may, by the ſlighteſt preſſure on the leading ſide ſtrap by his hand, cauſe it to ſhift upon the other pulley; but as this is not done inſtantly, it communicates the motion to the live pulley by degrees; for at firſt ſhifting, it begins upon a very narrow ſurface of the pulley, which is, therefore, urged into motion, but without violence to the machine, as the ſtrap at firſt ſlips partially upon the ſurface of the live pulley, and this, as we have before ſtated, cauſes the ſtrap to endeavour to eſcape from the pulley; but the attendant continues to preſs the ſtrap on the leading ſide, and force it to act upon the live pulley, which having attained its full velocity, and the ſtrap no longer ſlipping upon it, has no tendency to get off, unleſs the machine is overloaded, and then it will get off to the dead pulley. The live and dead pulley is very extenſively uſed in cotton machinery, and is a very excellent contrivance; the only objection to it being that the buſh in the centre of the idle pulley is liable to wear very looſe in a ſhort time. It is ſcarcely neceſſary to add, that the driving wheel for the ſtrap of the live and dead pulley muſt be as broad on its edge as both the live and dead pulley together; indeed, it is generally a long cylindrical drum, which receives many ſtraps for turning different machines.

A motion is frequently required in machinery, by which a wheel or axis is made to revolve in one direction for any required time, and then at pleaſure changed, ſo as to revolve in the other direction. Various means may be uſed for effecting this purpoſe. The moſt common is by means of two equal and ſimilar bevelled or contrate wheels, ſituated on the ſame axis, and their teeth towards each other. A third bevelled wheel is applied with its axis perpendicular to the former, and its teeth engaging at pleaſure with either of the two wheels, which, as they turn the ſame way round, and can be made to act at one or other of the ſides of the third wheel, ſo as to turn it in either direction, as it is engaged with either of the two wheels. This movement was applied by Mr. Smeaton to a machine he invented for drawing coals from coal-pits. In this the third wheel was a trundle, and could be, by a lever, made to work in the teeth of either of the cog-wheels which were mounted upon the axis of a water-wheel, and thus turned the trundle either way at pleaſure, to draw up or let down the baſkets or corves, which were ſuſpended from a drum upon the axis of the trundle. Some mechanics have conſtructed the contrivance in a different manner, by fitting the two wheels upon a circular part of their ſpindle, and ſuffering them to turn round freely upon it. Their teeth are always engaged with the teeth of the third wheel, and, therefore, they are always revolving in oppoſite directions, and either can at pleaſure be connected with the axis by a ſliding clutch-box, but which is not long enough to engage both at once. The axis can, by this means, be made to revolve in the direction of either wheel at pleaſure, by ſliding the clutch-box towards that wheel.

We have ſeen a very ingenious application of the live and dead pulley to this purpoſe, for a crane in a cotton mill, to take up and down the goods, work-people, &c. It was invented by Mr. Henry Strutt, and has been applied in his cotton mills at Belper, Derbyſhire. In this machine it was neceſſary to have a motion which could be turned either way at pleaſure, to draw up or let down the baſket; but the double wheel-work above deſcribed was evidently improper, from the ſudden jerk it would have given at the inſtant of changing the motion. It was effected in this manner: an axis which gave motion to the crane barrel, has two pair of live and dead pullies upon it, and alſo a brake wheel to ſtop the motion, which is ſituated between the two pair: an endleſs ſtrap is conducted to each pair, being turned by a long drum placed parallel to the axis of the pullies, and kept in conſtant motion by the mill. One of theſe endleſs ſtraps is croſſed between

between the drum and its pullies, but the other is not, therefore one pair of the live or dead pullies are always revolving in one direction, and the others are turning in an oppoſite way. Both ſtraps are conducted through guides fixed to a ſliding rail, by which the ſtraps can be ſhifted both at once, ſideways. When this rail is in a poſition that the ſtraps are both upon their dead pullies, the axis and brake wheel are at reſt, and in this poſition the rail has a tendency to remain, unleſs forced by hand. On moving the rail one way from the quieſcent point, one of the ſtraps is thrown on its live pulley, and the ſpindle turns with it, winding up the baſket. By moving the rail in the other direction beyond its quieſcent point, this ſtrap is ſhifted on to its dead pulley, and becomes inactive; but the other ſtrap operates on its live pulley, to turn the ſpindle in the oppoſite direction, and lets down the baſket. We ſhall deſcribe this very uſeful and curious machine in its place among the cotton machinery. See MANUFACTURE *of Cotton*.

Logwood raſping engines, ſcrew preſſes, and ſome other machines, require a motion to work them forwards to a certain extent, and then the direction is to be reverſed to draw them back, which requires but very little power to effect it. In this caſe the motion may be effected by a pair of cog-wheels turning each other, and thus communicating the motion for one direction in which it is to perform the work. A couple of pullies are fixed on the reſpective axes near the cog-wheels, and an endleſs ſtrap connects them, but the ſtrap is ſo long, that when the cog-wheels are in gear, the ſtrap hangs ſlack, and does not operate: but to reverſe the movement, the ſockets for one of the gudgeons of the driving ſpindle or axis is made to ſhift, that the diſtance between the centre of the two wheels may be increaſed, ſo as to diſengage the teeth of the wheels, and the ſtrap becomes tight, and turns the wheels back; but on bringing the wheels together again, the ſtrap becomes ſlack, and the wheels reſume their original courſe.

Screws are, of all the mechanical powers, the moſt frequently uſed in machines, though not always as moving parts, being chiefly introduced for uniting and retaining the parts. They are not ſo conſtantly employed as acting movements, on account of their friction, and the trouble of making them; they are, nevertheleſs, a very uſeful agent on many occaſions, and poſſeſs the advantage of accurately retaining any movement they make, and producing an extremely ſlow motion with eaſe, and, when it is required, with the moſt perfect accuracy. No engineer will employ ſcrews for a rapid motion, as their friction and great wear renders them unfit for ſuch ſituations. To the endleſs ſcrew acting on the teeth of cog-wheels, this objection does not apply ſo forcibly, becauſe the great number of teeth on which the ſcrew operates ſucceſſively, do not wear ſo faſt as the nut of a female ſcrew would under the ſame circumſtances, and the friction is far leſs, becauſe the ſcrew is not encloſed all round its thread. The endleſs ſcrew or worm is uſeful on many occaſions to obtain a ſlow motion, which it does in a very ſimple manner; but, for the purpoſe of obtaining a quick motion, it ſhould never be uſed, on account of the friction and conſequent wear. This is ſeen in the common roaſting jack.

In many ſituations in which moving ſcrews are uſed, the ſame effects may be produced in the moſt ſimple and convenient manner by Mr. Bramah's method of producing and applying a more conſiderable degree of power to all kinds of machinery requiring motion and force, than by any means at preſent practiſed for the purpoſe. This method, for which, on the 31ſt of March 1796, he obtained a patent, conſiſts in the application of water, or other denſe fluids, to various engines, ſo as, in ſome inſtances, to cauſe them to act with immenſe force; in others, to communicate the motion and powers of one part of a machine to ſome other part of the ſame machine; and laſtly, to communicate the motion and force of one machine to another, though removed to a great diſtance from each other, and where their local ſituations preclude the application of all other methods of connection. The principle of this invention is the ſame with the hydroſtatic paradox, but its various applications to uſeful purpoſes is due to Mr. Bramah. The ſimpleſt form is for a preſs, or machine, to raiſe an enormous weight to a ſmall height: a metallic cylinder ſufficiently ſtrong, and bored perfectly ſmooth and cylindrical, has a ſolid piſton fitted into it, which is made perfectly water tight, by leather packing round its edge, or other means uſed in hydraulic engines. The bottom of the cylinder muſt be made ſufficiently ſtrong, with the other parts of the ſurface, to reſiſt the greateſt ſtrain which can ever be applied to it. In the bottom of the cylinder is inſerted the end of a ſmall tube, the aperture of which communicates with the inſide of the cylinder, and introduces water or other fluids into it: the other end of the pipe communicates with a ſmall forcing pump, by which the water can be injected into the cylinder under its piſton: the pump has of courſe valves to prevent the return of the water. Now ſuppoſe the diameter of the cylinder to be twelve inches, and the diameter of the piſton of the ſmall pump or injector only one quarter of an inch, the proportion between the two ſurfaces or ends of the ſaid piſtons will be as 1 to 2304; and ſuppoſing the intermediate ſpace between them to be filled with water, or other denſe and incompreſſible fluids, any force applied to the ſmall piſton will operate upon the other in the above proportion, *viz.* as 1 to 2304. Suppoſe the ſmall piſton or injector to be forced down when in the act of forcing or injecting with a weight of 20 cwt. which can eaſily be done by means of a long lever, the piſton of the great cylinder would then be moved up, with a force equal to 20 cwt. multiplied by 2304. Thus is conſtructed a hydro-mechanical engine, whereby a weight amounting to 2304 tons can be raiſed by a ſimple lever, in much leſs time through equal ſpace, than could be done by any apparatus conſtructed on the known principles of mechanics, and it may be proper to obſerve, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being uſefully extended beyond a certain degree, but in machines acted upon, or conſtructed on this principle, every difficulty of this kind is obviated, and their power ſubject to no finite reſtraint. To prove this, it will be only neceſſary to remark, that the force of any machine acting upon this principle can be increaſed, *ad infinitum*, either by extending the proportion between the diameter of the injector and the great cylinder, or by applying greater power to the lever actuating the ſmall pump. On this principle very wonderful effects may be produced inſtantaneouſly, by means of compreſſed air. Suppoſe a large cylinder, furniſhed with a piſton in the ſame manner as before deſcribed, a globular veſſel is uſed, made of copper, iron, or other ſtrong material, capable of reſiſting immenſe force, ſimilar to thoſe uſed for air guns: it has a ſtrong tube of ſmall bore, in which is a ſtop-cock: one of the ends of this tube communicates with the great cylinder beneath its piſton, and the other end with the globe. Now ſuppoſe the great cylinder to be of the ſame diameter as that before deſcribed, and the ſmall tube equal to one quarter of an inch diameter, which is the ſame as the injecting pump before-mentioned for the preſs: then ſuppoſe that air is injected into the globe (by the common methods) till it preſſes againſt the cock with a force equal to 20 cwt. which can be done; the conſequence will be, that when the cock is opened, the piſton will be inſtantly moved in the great cylinder, with a power or force equal to 2304 tons, and it is obvious, as in the caſe before-mentioned, that any other unlimited degree of force may be acquired by machines or engines thus conſtructed. By the hydroſtatic principle, the power and motion of any machine may be transferred or communicated to another, let their diſtance and local ſituation be what they may. Suppoſe two ſmall tubes or cylinders, in the inſide of each of which is a piſton made water and air-tight, a tube may be conveyed under ground or otherwiſe, from the bottom of one cylinder to the other, to form a communication between them, notwithſtanding their diſtance be ever ſo great. Let this tube be filled with water, or other fluid, until it touches the bottom of the two piſtons; then, by depreſſing the piſton of one cylinder, the piſton of the other will be raiſed. The ſame effect will be produced, *vice verſâ;* thus bells may be rung, wheels turned, or other machinery put inviſibly in motion by a power being applied to either cylinder.

By theſe means, it is obvious, that moſt commodious machines of prodigious power, and ſuſceptible of the greateſt ſtrength, may readily be formed. If the ſame multiplication of power be attempted by toothed-wheel pinions and racks, it is ſcarcely poſſible to give ſtrength enough to the teeth of the racks, and the machines become very cumberſome, and of great expence. But Mr. Bramah's machine may be made abundantly ſtrong in very ſmall compaſs. It only requires very accurate execution. The hydroſtatic principle on which it depends has been well known for nearly two centuries, and it is a matter of ſurpriſe that it has never before been applied to any uſeful practical purpoſe.

The application which Mr. Bramah has made of this truly valuable principle is very general: it was firſt applied for preſſes inſtead of large ſcrews, for which purpoſe it is greatly ſuperior in every reſpect. Preſſes being generally moved by the ſtrength of men alone, the ſaving of power becomes a great object; and this it accompliſhes, having no proportion of the friction of the ſcrew, and immenſely greater power. In a ſcrew-preſs, it requires nearly as much labour to unſcrew as to ſcrew it up, an evidence of the enormous friction of a ſcrew, when acting againſt a great preſſure: but the hydroſtatic-preſs only requires a cock to be opened to let out the water from beneath the piſton, which then deſcends quickly, by its own gravity, or the elaſticity of the ſubſtances under the preſſure. But the greateſt convenience of the hydroſtatic principle is, that its power can ſo eaſily be tranſmitted to any diſtance, and in any direction, by means of pipes conducted along in ſituations where all other means of conveying the motion would be complicated, and expenſive in the extreme. Thus, in a large paper-mill, an injecting-pump may be kept in conſtant action by the water-mill, or ſteam-engine, and inject water into an air-veſſel, from which pipes are conducted to preſſes in all parts of the mill, and by ſimply opening a cock at any preſs, any required preſſure will be inſtantly given by the elaſticity of the confined air operating on the enlarged ſurface of the piſton of any preſs. The air-veſſel has, of courſe, a ſafety-valve, to allow the eſcape of the water when the preſſure becomes ſo great as to endanger the rupture of any of the veſſels; for it is to be obſerved, that the power of this principle is irreſiſtible, when the pump is worked by a mill, and will burſt any veſſels, without the leaſt appearance of ſtrain on the moving parts of the pump.

In Mr. Bramah's extenſive work-ſhops at Pimlico, and another at Mill-Bank, London, the ſteam-engines which turn the lathes, boring-machines, planing-machines, &c. work a ſmall injecting-pump, as above-mentioned, and ſmall copper pipes are laid to every part of the works, and by cocks admitting it into various cylinders, many powerful operations are performed: it works an immenſe preſs for bending ſtrong iron bars, or breaking caſt-iron for the foundery. It moves the carriage of the planing-engine; and he has brought the methods of packing the cylinders to ſuch perfection, that they are employed to make the moſt delicate adjuſtments in the parts of the machine. (See a full deſcription of this in PLANING *Engine*, and alſo PRESS, *Hydroſtatic.*) In another part of the factory, it works a crane for lifting the heavieſt goods, by merely opening a cock, and lowers them down, by opening another, with the utmoſt ſafety. A very large *Flood-gate* is alſo raiſed up by two cylinders. (See that article.) It may be uſed for turning the bridges of canals. (See CANAL.) On the whole, we cannot conclude this article, without recommending the hydroſtatic principle very ſtrongly to engineers, as a method the moſt perfect of all others of communicating motion, which is to act only for ſhort extents, or with great power, as it can ſo eaſily be conducted through any circuitous rout, and loſes ſo little power by friction. The eaſe with which it is relieved from the action, or cauſed to operate in a contrary direction, is not its ſmalleſt advantage; and by means of the air-veſſel the power may be accumulated while the machine is preparing for action, and then an immenſe power ſuddenly given. We have little doubt the hydroſtatic-preſs would anſwer the beſt of any method for expreſſing oil. The preſent oil-preſs is deſcribed under OIL-*Mill*, and operates by a wedge, driven by repeated blows of a heavy ſtamper. The method is ingenious; but great part of the power is expended in friction, as is evident from the wedge requiring nothing to retain it, as it is driven, the friction over-balancing all the re-action of the ſubſtances preſſed.

A motion is very frequently required in machinery for giving to any piece of wheel-work an increaſed or diminiſhed velocity at pleaſure. The moſt complete of theſe are the EXPANDING *Riggers* (ſee that article); but many other means may be employed. Thus, on two parallel ſpindles, which are to turn each other, place a number of wheels, increaſing in ſize by regular ſteps, the ſmalleſt wheel of one ſpindle being oppoſite to the largeſt of the other. The ſame endleſs ſtrap will fit any pair of them, and give a great variety of powers and velocities: the ſame may be effected by having a number of cog-wheels; and, inſtead of a ſtrap, uſing an intermediate cog-wheel, which can be applied to connect any pair of the wheels at pleaſure. A very ingenious application of double cones is uſed in a cotton-machine, called the double ſpeeder. See MANUFACTURE *of Cotton*, alſo Mr. Braithwate's CRANE.

It is very cuſtomary to add what is called a fly to machines. This is a heavy diſk or hoop, or other maſs of matter, balanced on its axis, and ſo connected with the machinery, as to turn briſkly round with it. This may be done with the view of rendering the motion of the whole more regular, notwithſtanding unavoidable inequalities of the accelerating forces, or of the reſiſtances occaſioned by the work: it then becomes a regulator. Suppoſe the reſiſtance to a machine extremely unequal, and the impelling power perfectly conſtant; as when a bucket-wheel is employed to work one pump; when the piſton has ended its working-ſtroke, and while it is going down the barrel, the power of the wheel being ſcarcely oppoſed, it accelerates the whole machine, and the piſton arrives at the bottom of the barrel with conſiderable velocity; but in the riſing again, the wheel is oppoſed by the column of water now preſſing on the piſton: this immediately retards the wheel; and when the piſton has reached the top of the barrel, all the acceleration is undone, and is to begin again. The motion of ſuch a machine is very hobbling; but the ſurplus of accelerating force, at the beginning of a returning ſtroke, will not make ſuch a change in the motion of the machine, if we connect the fly with it; for the accelerating momentum is a determinate quantity: therefore, if the radius of the fly be great, this momentum will be attained by communicating a ſmall angular motion to the machine. The momentum of the fly is as the ſquare of its radius, therefore it reſiſts acceleration in this proportion; and although the overplus of power generates the ſame momentum of rotation in the whole machine as before, it makes but a ſmall and imperceptible addition to its velocity. If the diameter of the fly be doubled, the augmentation of rotation will be reduced to one-fourth. Thus, by giving a rapid motion to a ſmall quantity of matter, the great acceleration during the return-ſtroke of the piſton is prevented. This acceleration continues, however, during the whole of the returning ſtroke, and at the end of it the machine has acquired its greateſt velocity. Now, the working ſtroke begins, and the overplus of power is at an end. The machine accelerates no more; but if the power is juſt in equilibrium with the reſiſtance, it keeps the velocity which it has acquired, and is ſtill more accelerated during the next returning ſtroke. But now, at the beginning of the ſubſequent working-ſtroke, there is an overplus of reſiſtance, and a retardation begins and continues during the whole riſe of the piſton; but it is inconſiderable in compariſon of what it would have been without the fly: for the fly, retaining its acquired momentum, drags forwards the reſt of the machine, aiding the impelling power of the water-wheel. It does this by all the communications taking into each other in the oppoſite direction; the teeth of the intervening wheels are heard to drop from their former contact on one ſide, to a contact on the other. By conſidering this proceſs with attention, we eaſily perceive that in a few ſtrokes the overplus of power, during the returning ſtroke, comes to be ſo adjuſted to the efficiency, during the working ſtroke, that the accelerations and retardations exactly deſtroy each other, and every ſucceeding ſtroke is made with the ſame velocity, and an equal number of ſtrokes is made in every ſucceeding minute. Thus the machine acquires a general uniformity with trifling periodical inequalities. It is plain, that by ſufficiently enlarging either the diameter, or the weight of the fly, the irregularity of the motion may be rendered as ſmall as we pleaſe. It is much better to enlarge the diameter: this preſerves the friction more moderate, and the pivots wear leſs. For theſe reaſons, a fly is, in general, a conſiderable improvement in machinery, by equalling many exertions that are naturally very irregular. Thus a man, working at a common windlaſs, exerts a very irregular preſſure on the winch. In two of his poſitions in each turn, he can exert a force of near ſeventy pounds without fatigue, but in others he cannot exert above twenty-five; nor muſt he be loaded with much above this in general. But if a large fly be connected properly with the windlaſs, he will act with equal eaſe and ſpeed againſt thirty or even forty pounds.

If any permanent change ſhould happen in the impelling power, or in the reſiſtance, the fly makes no obſtacle to its production in its full effect on the machine, and it will be obſerved to accelerate or retard uniformly, till a new general ſpeed is acquired, exactly correſponding with this new power and reſiſtance. Many machines include in their conſtruction movements which are equivalent with this intentional regulation, a flour-mill for example. There is another kind of regulating fly, conſiſting of wings whirled briſkly round till the reſiſtance of the air prevents any great acceleration. This is a very bad one for a working machine, for it produces its effect by really waſting a part of the moving power. Frequently it employs a very great and unknown part of it, and robs the proprietor of much work. It ſhould never be introduced into any machine employed in manufactures, except in the inſtance of letting down heavy weights, where a waſte or re-action to power is the object.

Some rare caſes occur where a very different regulator is required, when a certain determined velocity is found neceſſary: in this caſe, the machine is furniſhed at its extreme mover with a conical pendulum, conſiſting of two heavy balls hanging by rods, which move in very nice and ſteady joint at the top of a vertical axis. It is well known, that when this axis turns round, with an angular velocity ſuited to the length of thoſe pendulums, the time of a revolution is determined.

Thus, if the length of each pendulum be $39\frac{1}{5}$ inches, the axis will make a revolution in two ſeconds very nearly. If we attempt to force it more ſwiftly round, the balls will recede a little from the axis, but it employs as long time for a revolution as before; and we cannot make it turn ſwifter, unleſs the impelling power be increaſed beyond all probability: in which caſe, the pendulum will fly out from the centre till the rods are horizontal, after which every increaſe of power will accelerate the machine very ſenſibly, as it then becomes a ſimple fly. Watt and Boulton have applied this contrivance with great ingenuity to their ſteam engines when they are employed for driving machinery for manufactures which have a very changeable reſiſtance, and where a certain ſpeed cannot be much departed from without great inconvenience. They have connected this receſs of the balls from the axis (which gives immediate indication of an increaſe of power, or a diminution, or reſiſtance,) with a cock, which admits the ſteam to the working cylinder. The balls flying out cauſe the cock to cloſe a little, and diminiſh the ſupply of ſteam, if the impelling power diminiſhes the next moment, and the balls again approach the axis, and the rotation goes on as before, although there may have occurred a very great exceſs or deficiency of power. The ſame contrivance may be employed to raiſe or lower the feeding ſluice of a water-mill employed to drive machinery. (See Mill.) Suppoſe all reſiſtance removed from the working point of a machine furniſhed with a very large or heavy fly, immediately connected with the working point; when a ſmall force is applied to the impelled point of this machine, motion will begin in the machine, and the fly begin to turn, continue to preſs uniformly, and the machine will accelerate. This may be continued till the fly has required a very rapid motion. If, at this moment, a reſiſting body be applied to the working point, it will be acted on with very great force; for the fly has now accumulated, in its circumference, a very great momentum.

If a body were expoſed immediately to the action of this circumference it would be violently ſtruck, much more will it be ſo, if the body be expoſed to the action of the working point, which perhaps makes one turn while the fly makes a hundred. It will exert a hundred times more force (very nearly) than at its own circumference. All the motion which has been accumulated in the fly, during the whole progreſs of its acceleration, is exerted in an inſtant at the working point, multiplied by the momentum, which depends on the proportion of the parts of the machine. It is thus that the coining preſs performs its office; nay, it is thus that the blackſmith forges a bar of iron. Swinging the great ſledge hammer round his head, and urging it with force the whole way, this accumulated motion is at once extinguiſhed by impact on the iron. It is thus we drive a nail; and it is thus, that by accumulating a very moderate force exerted during four or five turns of a fly, the whole of it is exerted on a punch, ſet on a thick plate of iron, ſuch as is employed for the boilers of ſteam engines, and the plate is pierced as if it were a piece of cheeſe. This accumulating power of a fly has occaſioned many, who think themſelves engineers, to imagine, that a fly really adds power or mechanical force to an engine; and, not underſtanding on what its efficacy depends, they often place the fly in a ſituation where it only added a uſeleſs burden to the machine. If intended for a mere regulator, it ſhould be near the firſt mover: if it is intended to accumulate force in the working point, it ſhould not be far ſeparated from it. In a certain ſenſe, a fly may be ſaid to add power to a machine, becauſe by accumulating into the exertion of one moment the exertions of many, we can ſometimes overcome an obſtacle that we never could have balanced by the ſame machine unaided by the fly. See FLY-WHEEL.

It is this accumulation of force which gives ſuch an appearance of power to ſome of our firſt movers. When a man is unfortunately catched by the teeth of a paltry country mill, he is cruſhed almoſt to mummy. The power of the ſtream is conceived to be prodigious, and yet we are certain, upon examination, that it amounts to the preſſure of no more than fifty or ſixty pounds; but this force has been acting for ſome time, and there is a millſtone of a ton weight whirling twice round in a ſecond. This is the force that cruſhed the unfortunate man; and it required it all to do it, for the mill ſtopped. We have been informed of a mill in the neighbourhood of Elbingroda, in Hanover, where there was a contrivance which diſengaged the millſtone when any thing got entangled in the teeth of the wheels. On being tried with a head of cabbage, it cruſhed it, but not violently, and would, by no means, have broken a man's arm.

It is hardly neceſſary to recommend ſimplicity in the conſtruction of machines. This ſeems now ſufficiently underſtood. Multiplicity of motions and communications increaſe friction; augment the unavoidable loſſes by bending and yielding in every part; expoſe all the imperfections of workmanſhip; and have a great chance of being indiſtinctly conceived; and are therefore conſtructions without ſcience. We ſhall conſider this object as applied to large machinery under MILL *Work*.

MACHINERY *for manufacturing Cotton*. See MANUFACTURE *of Cotton*.
